### Abstract

This report describes the current status of personnel scheduling management in Washington State Department of Transportation's construction field offices, assesses the current status, and outlines a conceptual personnel scheduling management system that may improve the existing situation. The report develops a model of personnel scheduling that becomes the basis for comparing current field office practices. Instead of a unified personnel scheduling management system for all the offices, four general levels of scheduling, labeled Informal, "To Do" List, Bar Chart and Network, were found. These are described in the report in detail.

The assessment confirmed the existence of several constraints on personnel scheduling at the construction field office level. These constraints limit the field office Project Engineer in managing personnel schedules by restricting the schedule balancing options normally available in project management. This is particularly true with respect to the project dimension of the scheduling model. Most of the constraints come from outside the field office.

A unified personnel scheduling management system concept is outlined, based on patterns of scheduling already in existence at the field offices. Despite the constraints, this system concept is expected to provide most Project Engineers with ways to improve their current personnel scheduling practices. Three design approaches, a manual approach, a spreadsheet approach and a network approach, are suggested.

### Key Words

- Personnel scheduling
- Personnel management
- Construction personnel scheduling

SUMMARY

*Personnel scheduling management* is defined here as the matching of staff resources with projects so that the projects are completed within reasonable time and budget limits while the staff are fully utilized. This study focuses on the current state of personnel scheduling management systems in the Washington State Department of Transportation (referred to as WSDOT and the Department) construction field offices. It is assumed that, though all of the field offices use some level of scheduling, there could be more effective, systematic and less reactive ways of doing personnel scheduling at this level. The study finds that the Project Engineers are scheduling under a variety of constraints and concerns that directly impact their ability to do long-range planning and respond quickly to short-range schedule changes. In response to the findings, a unified personnel scheduling management system has been conceived, with three suggested approaches for design and implementation that would fit into many of the project offices.

To develop the final personnel scheduling management system concept, an investigation which included a questionnaire sent to the Project Engineers and interviews was completed to understand how personnel scheduling is done currently. As part of the investigation, the structural placement of projects, personnel and the construction field office itself within the Department was established, interrelationships were identified and a model of scheduling for the construction field offices was developed.

The majority of the information from the questionnaires and interviews shows that the Project Engineers are doing restricted scheduling under numerous constraints. These constraints can be generally categorized as:

- current notification procedures of project assignment and scope to the field office;
- limitations on project management based solutions;
• Inaccurate contractors' progress schedules and contractors' updates during construction;
• Limitations on numbers of personnel available to the construction field office; and
• Attitudes and perceptions of the Project Engineers themselves about the construction field office, its position, the Department and their ability to deal with the problems they encounter.

The first three of these constraints directly affect the project side of scheduling. The first four originate from outside the construction field office and are not under the Project Engineer's control to change.

The effects of these constraints are that, when the model of scheduling is applied to the actual field office situation, the Project Engineers find themselves unable to make use of a major portion of the solutions that would normally be available to balance their personnel schedules. The model indicates that three areas of scheduling adjustment, adjusting the resource pool, adjusting the resource assignments and adjusting the task schedules, should be available to the project manager on any project. However, this report suggests that the constraints do not allow the Project Engineer to adjust the project task schedules at all because they come from outside the field office, while the resource pool and resource assignments are partially limited by communications difficulties and perceptions.

The response to the constraints has been a variety of levels of personnel scheduling, developed in an attempt to focus on projects while adjusting personnel, as well as less interest in longer range planning, which tends to be isolated from operations, or shorter range, scheduling. Four basic scheduling level categories are identified: informal, "to do" lists, bar charts and networks, with variations on each. Some of the techniques used, while they eventually respond by putting people with projects over time, are missing elements or detail levels so that true schedules are not created. Other techniques are highly crafted examples of what can be done in spite of the constraints.

Based on these investigations, a unified personnel scheduling management system is outlined. This system would include the ability to do both planning and operations scheduling, interconnecting the two. Three approaches to further design and implement this system are proposed, one manual and two computerized. All of the approaches utilize the steps to scheduling found in the conceptual exploration of the system, many of which are already in place in the construction field offices.
CONCLUSIONS

Given the findings summarized above, the following conclusions are drawn:

1. The constraints that are operating will continue to restrict any personnel scheduling management system in the construction field offices.

2. The system proposed here in conceptual form is expected, when implemented, to improve personnel scheduling management and decisions by standardizing and, in some cases, automating procedures, thus alleviating some of the stresses associated with reactive management.

3. The three approaches fulfill the system objectives to varying degrees. The manual system can be implemented without requiring additional expertise, but because of time constraints, is severely limited in its ability to be easy to use, minimize reactive management and effectively use personnel. The spreadsheet system minimizes the manual calculations required in scheduling and has less time constraints, but requires a greater set up time and more expertise for the designer. The network system requires little physical system development and offers the easiest updating methods, but the programs can be time consuming in learning applications especially because the reports from this system are conceptually different than the proposed approach.

RECOMMENDATIONS

The following recommendations are divided into those that can be implemented by the construction field office directly and those that are dependent on outside actions for implementation.

Inside the Construction Field Office, it is recommended that

1. one or more construction field offices design and implement one or more of the proposed systems;

2. implementation of the proposed systems be done in coordination with the technical support personnel available at DOT, with both construction field office and technical staff involved rather than only one or the other;

3. after the various system approaches have been designed and tested, they be installed in any interested field office; and
4. construction field office personnel experienced in the use of any of the systems help work out formal training sessions to teach both the system concepts and practical experience in system implementation and use.

Outside the Construction Field Office, it is recommended that

1. a study be done to establish whether exclusive assignment of a micro to the Project Engineers for use in scheduling would be the best way to encourage implementation of a scheduling system;

2. steps be taken to alleviate the problem related to construction personnel input into design, which input is not now available in a timely manner; such steps could include, but not be limited to
   - inviting construction inspectors with some experience to design team meetings when project scope and/or design is being discussed,
   - inviting input from the tentatively assigned construction field office when alternatives have been chosen for constructability of the designs, and
   - inviting construction field office input into special designs for constructability and understandability of the plans.

3. training in CPMS be more widely available to the entire field office system;

4. headquarters and district management encourage and support the Project Engineers in enforcing the Standard Specifications and Special Provisions where contractors' progress schedules are concerned [1, 2];

5. contractors progress schedules and updates be required to be more uniform as well as more readily available to the construction field office; and

6. project costs be related more directly to personnel schedules through a revised method of estimating project costs.
INTRODUCTION

REPORT ORGANIZATION

This report is aimed at developing and describing alternatives to help construction field offices within the Department of Transportation manage their personnel. The methodology used to develop these alternatives and recommendations is divided into the following sections:

- **Statement of the Problem and Study Objectives.** The problem to be discussed is presented along with the objectives to be reached by this study.

- **The Construction Field Office and Scheduling Issues.** A general model of what personnel scheduling management entails within the construction field office is described.

- **Summary of Current Field Office Practices.** This section describes the current state-of-the-art of personnel scheduling in construction field offices.

- **Analysis of the Current State of Personnel Scheduling Management.** The model, the collected data and the descriptive information from the Project Engineers are used to assess the personnel scheduling management systems found in the construction field offices.

- **Preliminary Design Concepts for a Personnel Scheduling Management System.** A general description of the system design concept objectives and requirements for the personnel scheduling management system are presented here. Products (or reports) for planning and operations as well as the transforming processes required to produce the reports are described.

- **System Design Approaches.** Using the preliminary design concepts, three alternative approaches to system design with varying levels of complexity are proposed and assessed in terms of meeting the objectives established previously. Existing software is used to help produce some of the systems.

**STATEMENT OF THE PROBLEM**

WSDOT is a state governmental agency that has been mandated to provide a multimodal transportation system which meets the social and economic needs of the state [3]. To fulfill the mandate, WSDOT designs, constructs and maintains various facilities statewide, such as roadways and alternate transportation modes.
The Department’s construction section oversees the building of new facilities and the replacement of older facilities to the best known standards and specifications. The responsibility for maintaining these standards in construction lies in the on-site inspection of the various projects, which are handled through small units called construction field offices (also called project offices and field offices).

Headed by a Project Engineer, each field office is responsible for administering the contracts by ensuring that the contractors properly construct departmentally designed projects within a district. All aspects of construction management, including finances (to a certain degree), inspection, testing and records are included within this office. As part of this, the Project Engineer must be able to balance all of the projects assigned to him with all of the resources given him in a cost-effective and timely manner. To do this, he must undertake what can be termed personnel management.

Personnel management at the construction field office level is, both currently and historically, a significant concern. No uniform personnel scheduling management system is available to the project offices, and personnel management methods as well as schedule controls are lacking. Project engineers need to handle constant schedule changes that involve altering or adjusting personnel schedules and which are generated by contractors, the public, the Department, employees and others.

Frequently, the project office develops a method of dealing with scheduling that resembles crisis management, here called reactive management. Scheduling is handled in immediate reaction to a situation rather than as an anticipated and planned response. When this type of method develops in an office, the Project Engineers seem to come to expect that they must operate in a reactive manner, neglecting planning.

**STUDY OBJECTIVES**

The Technical Documentation provides and this report summarizes

- an understanding of the current state of personnel scheduling in the WSDOT construction field offices;
- an understanding of the problems that the construction field office Project Engineers face in personnel scheduling;
- an assessment of the methods used to deal with personnel scheduling; and
- preliminary designs of systems that could help field office Project Engineers manage personnel scheduling in a more effective, systematic and less reactive manner.
The problems encountered by field offices will not disappear. Indications are that they will worsen with simultaneous shortages of funds and deteriorating highways. Response to these problems must be more effective, cost-conscious and timely.

Assumptions formulated for this report include the following:

1. that a more uniform personnel scheduling management system would be able to relieve the Project Engineer of some of the time consuming aspects of personnel scheduling and thus free him to do more direct contract administration;

2. that the personnel scheduling management system employs two types of scheduling: planning and operational, functioning simultaneously in the field office;

3. that the current state-of-the-art of personnel scheduling management at the construction field office level is based more on reactive management than on a treatment of the whole system based on foreknowledge and assessment;

4. that the reactive response is one of the root causes for the lack of a personnel scheduling management system;

5. that it is possible to improve procedures and systems for planning and managing resources (personnel, time, equipment and funds) so that an adequate response to scheduling changes can be formulated and acted on quickly and effectively;

6. that the system could be designed to fit into the current levels of scheduling found at the Department;

7. that systems currently in place, or simpler systems implemented from this study can be upgraded as the construction field office gradually increases its sophistication in personnel scheduling; and

8. that an improved system would increase productivity, decrease engineering cost overruns through earlier identification of them, and improve office morale and communications.
BACKGROUND:
THE CONSTRUCTION FIELD OFFICE AND SCHEDULING ISSUES

ORGANIZATIONAL STRUCTURE

WSDOT is organized as a hierarchical structure. Headquarters is concerned with the general administration of all aspects of the Department, formulating policies for the entire Department and setting district goals. Districts, of which there are six, are concerned with specific project and personnel management issues. Construction field offices, which are also hierarchical, are a specific type of office in the district that administers assigned contracts through a variety of tasks including inspection, testing materials and keeping records, using a variety of permanent and temporary staff members.

PROJECT CYCLES AND THE CONSTRUCTION FIELD OFFICE

Projects at DOT go through five phases to get from start to finish: conception, definition, production, operations and divestment [5]. Two distinct project sub-cycles exist within DOT. The first is exclusively a design cycle and encompasses the first three project phases, while the second is exclusively a construction cycle involving the last two project phases. The dividing point between the two phases is the ad date, which for design is the date the project is expected to be complete for advertisement, and which for construction marks the beginning of contract administration.

Conception is a complex interaction between headquarters, the districts, the Transportation Commission and the legislature which results in the prioritization and programming of projects. After a project is programmed, the District defines it by creating the Design Report which includes the design concept, recommendations for design alternatives, and various special studies required by the project's scope. After the Design Report is completed and headquarters has approved it, the District produces the Plans, Specifications and Estimates (PS&E), which include the drawings and other information used by the contractors to construct the project. The construction field office is not expected to be involved in these phases, though PS&E theoretically would be reviewed by a construction field office beginning about two months prior to ad.

The construction phase begins with operations, which is project inspection as construction is done; staffing levels for each project change in response to contractor needs as construction progresses. The final
phase, *divestment*, is the completion of the final estimates (required at headquarters 45 days after the contractor finishes) and final records (required as soon as possible after the project closes).

**PERSONNEL SCHEDULING IN CONSTRUCTION FIELD OFFICES**

Most projects are ready to construct when the field office receives them, and personnel with a variety of skills in inspection are available to ensure timely construction to specifications. To match the personnel and projects required for construction requires the generation of a balanced personnel schedule. Here, a generic model of scheduling is developed and is used as a focal point for discussion.

**Elements of Scheduling**

Scheduling combines and balances three elements: personnel, projects and time. The typical approach to creating a complete personnel schedule includes

1. Projects fixed in time based on ad date and duration;
2. Office personnel assigned to projects; and
3. Combining the above to assess how personnel are used over time.

"Optimizing" the schedule is done by controlling the occurrence of projects in time and/or the assignment of personnel to projects.

**Model of Personnel Scheduling**

Figure 1 illustrates the concepts presented as elements of scheduling. Projects and human resources are apportioned to the field office from other departmental levels. The Project Engineer assigns his available resources to the office's projects, resulting in a personnel schedule.

Figure 2 presents a more refined picture of the project office process, which reflects both planning and operational considerations. In *planning*, expected future projects and anticipated human resources are assigned together over a range of time and balanced with the use of available information. If a balance is not achieved on the first iteration, all the elements are open to alteration. The expected final result is the preliminary personnel schedule.

*Operations* scheduling is used when projects are under way and is a dynamic, constant balancing of personnel assignments. Continual reassessment is necessary as project schedules and available personnel
Figure 1. General Diagram of Personnel Scheduling within Field Office
change over the short term. During this assessment, or monitoring, the type of change taking place is
established, and appropriate adjustments made.

Methods for Creating a Personnel Schedule

On the basis of these dimensional elements, the two phases of personnel scheduling, and what the
Project Engineer perceives as his need for a personnel schedule, the Project Engineer chooses one of four
general levels of "scheduling" identified by Shawcroft [6] to create the best balanced match between people,
projects and time. The descriptions below are based on how each level characteristically handles the phases and
the elements of personnel scheduling. Whether the first two levels (informal and "to do" lists) can truly be
scheduling is questionable because they do not use all three elements of scheduling.

Informal: Mental. The Project Engineer associates personnel and projects in his mind to generate the
field office's personnel work load. Written forms of schedules of any kind are rare and reliance is placed on the
Project Engineer's memory. Formalized longer range scheduling is rare.

"To do" list: Formalized list of projects, tasks. Listed items are usually unrelated to each other. Key
personnel may be assigned to a project or task. Time may be involved, but only informally.
Figure 2. Flowchart of Planning and Operations Personnel Scheduling
**Bar chart:** Time added to list of projects, tasks. Time is considered essential to the schedule, and projects and personnel are assigned on a timeline. The charts created are generally static and cover fairly long periods. Project tasks are not related to each other, and updating is difficult.

**Network:** Relationships between tasks added. The effects of changes on one task can automatically propagate changes in following tasks related to the first task. Resource demand, because it is interconnected with tasks, also changes automatically as tasks change. Time is dynamic, so that both longer and shorter range scheduling are important. Updating is one of the keys to maintaining this level of scheduling.
CURRENT FIELD OFFICE PRACTICES

DATA COLLECTION METHODOLOGY

The methodology used to examine the issues of personnel scheduling management in construction field offices involved, first, a literature search to discover what previous experience might have been. This search unearthed much indirectly related material, but nothing that could direct the research.

Second, the methodology involved sending a questionnaire to and interviewing the field office Project Engineers. The objectives of the questionnaire and interviews were to

- determine existing personnel scheduling practices and procedures;
- identify scheduling problems and constraints; and
- obtain suggestions for what would be useful in a personnel scheduling management system.

Other states were also interviewed to compare WSDOT's personnel scheduling management techniques to theirs and possibly gain suggestions for potential solutions to the problems encountered. Detailed information is in the Technical Report.

CONSTRUCTION FIELD OFFICE LEVELS OF SCHEDULING

According to the information from the questionnaires and interviews, almost all the responding engineers and members of their staff were involved in some form of preliminary personnel scheduling (or planning), and virtually all of them attempted some form of operational personnel scheduling. Though usually informal, the operations phase also included some type of monitoring. Of the four levels of scheduling, 13 percent of the Project Engineers use informal levels, 44 percent use "to do" lists, 37 percent use bar charts and 6 percent use networks.

Planning

Generally, if the Project Engineers plan, they do so to determine the adequacy of personnel and equipment and to schedule people with projects. Planning schedules were done mostly at grosser detail levels, such as months or no time periods, gross task schedules, and key personnel assignments only.

Problems they encountered that they perceive as limiting the effectiveness of planning included the uncertainty of start dates, uncertainty of when project tasks would actually occur and lack of detailed project
schedules. These problems all focus on the project dimension of scheduling, and the data required to alleviate them must come from outside the field office. Areas such as lack of procedures for scheduling were not considered problems because the Project Engineer feels he can control them.

**Operations**

Similarly to planning, operations schedules were done at a fairly gross level of detail, with less documentation (only about a third write down an operations schedule). Those who document, however, used a greater level of time (weeks and months). About two-thirds of the Project Engineers also monitored all projects, usually to update schedules.

As with planning, problems such as lack of detailed, updated and reliable contractors' schedules, uncertainty of project activities' timing and lack of response time were important in limiting the use of personnel evenly over a year. Much of the data for these concerns is not under the Project Engineer's control. Those that the Project Engineer could control were not considered problems.

To solve the problems encountered in operations, the Project Engineers generally use solutions that alter the resource pool (such as adding temporary employees, overtime or borrowing crew) or the assignments. Fewer than half of the Project Engineers ask the contractor to adjust his schedule, the only non-resource altering solution mentioned.
DISCUSSION:
ANALYSIS OF THE CURRENT STATE OF PERSONNEL SCHEDULING MANAGEMENT

SYSTEMS OF SCHEDULING AT WSDOT

The Project Engineers do carry out purposeful personnel scheduling management at WSDOT. Characteristics common to all the systems found at the Department include

1. the delegation of day-to-day scheduling to the chief inspector or the project inspector, unless a crew change is required, at which point the Project Engineer becomes directly involved in the process;
2. the high level of distrust of the contractor's progress schedule and the written updates received; and
3. the reluctance of almost all Project Engineers to ask the contractor to alter his schedule.

Table 1 compares the typical system features and characteristics of the four systems mentioned as they are found at DOT.

THE LIMITATIONS OF THE CURRENT SYSTEMS

Two major restrictions limit the Project Engineer's ability to do personnel scheduling management. The first, and most important, restriction is that the Project Engineer is severely limited in his ability to balance his system. As illustrated by Figure 3, the Project Engineer cannot take advantage of the balancing techniques offered by the left side of the scheduling model, which concerns the ability to alter project task schedules. Control of the schedules used by the Project Engineer for planning and operations is in the hands of the design section of the Department and the contractor. The second restriction, affecting the resource pool, consists of difficulties in communication and perceptions about departmental policies.

Project Schedule Limitations

Resource Leveling

For the field office, resource leveling, an important aspect of scheduling, is essential for two reasons:

1. highs and lows caused by the seasonality of the construction process for contractors also affect the construction field office schedules; and
2. the Department limits each field office to a certain level of permanent staff somewhere between the peaks and valleys.

Combines planning and operations (unified system)  
Track contractor easily  
System enhanced easily  
Updates more easily  
Schedule available quickly | Setup time is long  
Level of detail and accuracy is affected by uncertainty of activity start dates |
Figure 3. Model of Scheduling: Limitations on the Construction Field Office
Major limitations affecting resource leveling for projects include that

- the construction field office does not know for certain about a project's assignment until two months (maximum, frequently less) before the ad date, leaving little time for the leveling, which begins to be required at least a year in advance;
- the field office does not control the ad or start date, both of which change frequently, quickly and with little prior notice, making resource leveling for more than in-house projects a futile exercise; and
- Project Engineers do not control contractors' progress schedules and so only guess the task schedule for resource leveling.

To partially solve this problem, the focus must shift from a concentration on projects to the resource pool. Also, a secondary task schedule not necessarily dependent on particular projects can be planned for slack times.

**Lack of Communications**

The construction field office is seldom fully informed about the project it will be inspecting until approximately two months before the ad date. This tends to limit the project office's planning to notifying headquarters of what the field office feels (guesses) it needs in the way of personnel and equipment for the next season. Many of the Project Engineers limit their view of planning deliberately to avoid having to deal with as many changes as are expected.

The solution to this problem may lie in a greater attention to the valid concerns of construction inspectors by design teams. The design team must become aware of the advantages of involving the construction personnel much earlier in the design process, perhaps at the Design Report stage.

**The Contractor's Progress Schedule**

Project schedules for operations within the field office are often partially based on the contractor's progress schedule. The contractor's progress schedule is supposed to tell what the contractor intends to do, approximately when in work days and what the critical work items are. However, many contractors' progress schedules are not very detailed or accurate and updates are infrequent. The inaccuracy of these schedules limit the field office's ability to create reliable schedules and the techniques available for adjusting the personnel schedule.
The solution to this problem will include holding more strictly to the contractors' progress schedule specifications that require accuracy and weekly updates. Enforcement of these specifications will require support from upper level construction personnel.

**Resource Pool Limitations**

These are generally caused by two problems: communications difficulties between district construction organizations and perceptions about departmental policies. The communications difficulties were not found statewide, and were generally influenced by rivalries, egocentricities and position protection attitudes. Policies perceived as restricting the Project Engineers' ability to schedule include design centralization (which takes away work during slower seasons), cutbacks in permanent staff (which causes lower inspection standards) and contractor accommodation as the main purpose for scheduling (which can strain the resource pool).

Solutions to these problems most likely lie outside the field office, through reestablishment of trust by greater communications at all levels. The initial movement would come from upper levels of management.
DISCUSSION:
PRELIMINARY DESIGN CONCEPTS FOR A
PERSONNEL SCHEDULING MANAGEMENT SYSTEM

SYSTEM OBJECTIVES

Five major objectives for improving personnel scheduling management surface when the scheduling model is used to explore the current personnel scheduling systems of the construction field office:

- **Improve personnel needs projects** by upgrading planning scheduling, incorporating minimal levels of project detail and personnel demand while remaining relatively easy to use and maintain.
- **Minimize reactive management** by upgrading operations scheduling, incorporating ways to see clearly the complete day-to-day tasks and available personnel in the sort term.
- **Maintain efficient use of resources** by upgrading resource scheduling to eliminate unnecessary resource peaks and valleys.
- **Documentation** by maintaining records that chronicle the relationship between project progress and personnel assignments and utilization.
- **Ease of use** by establishing methods of data collection, processing and reprinting that are understandable.

All of these objectives build on data, procedures and products already in use at field offices.

ESSENTIAL SYSTEM REQUIREMENTS

System Products

The basic system objectives could be met through the production of three standard reports:

- a Personnel Projections Schedule,
- a Quarterly Personnel Summary, and
- a Daily Personnel Assignments Schedule.

The first two would be specifically planning reports and the last would be an operational report.

Personnel Projections Schedule

Figure 4 illustrates the general format of this report. The scales would be at a low level of detail: time in weeks (or quarter-months) over a two-year period, personnel in crews and classification levels, and projects

at gross level of tasks. The two-year term has been chosen to represent the biennium unit used for much of the Department's planning. The four sections are the following:

Section 1. The bar chart, which would be the main schedule overview.

Section 2. A summary of the number of crews required for each time period.

Section 3. A table of the classification levels that make up each crew.

Section 4. A projection of the number of personnel needed in each classification level.

Quarterly Personnel Summary

This is a summary of the Personnel Projections Schedule specifically for district personnel planning. Figure 5 illustrates the Quarterly Personnel Summary report, which indicates the projected person-months needed in the field office for construction, location and administration.

Daily Personnel Assignments Schedule

Figure 6 illustrates this report's general format, a bar chart showing how each person is scheduled over four weeks. The scales would be at a fine level: time in days covering a four-week period, personnel by individual names and classification level, and projects broken into tasks at each point where the size or type of crew changes. Below the bar chart would be the project summary, which would list each project's tasks and total the number of personnel assigned daily to each task. Creation of the bar chart would require creation of two side reports that are then combined into the main schedule.

System Processing Overview

Planning Steps Summary

Figure 7 is a flow chart illustrating the process required to achieve both the Personnel Projections Schedule and the Quarterly Personnel Summary. The proposed system is not intended to cover specific individuals or highly detailed project tasks and must allow for two types of flexibility. The first is easily adjustable start and end dates that incorporate new information as it becomes available. The second is flexibility in producing the two reports, of which the second report is dependent on the first. Furthermore, the system must recognize variations in types of data available and permit the Project Engineers to use their own judgment in assessing future total crew needs for project tasks.

**Figure 5.** Quarterly Personnel Summary
Figure 6. The Daily Personnel Assignment Schedule
Figure 7. Flow Chart for Personnel Projections Schedule and Quarterly Personnel Summary
The process to achieve these schedules is initiated by the assignment of the project to the field office. Steps include:

- **The Calendar Step:** Place the project onto a master calendar, using a project identifier, the first date anyone in the office was expected to begin work on it, and a date for the project's completion. The information could be calculated from the add date.

- **The Task Breakdown Step:** Break the project into tasks that different crews would perform using the probable project progression and the estimated duration of the tasks estimated from the first step.

- **The Assignments Step:** Determine crew demand by project using information from the first two steps. Partial weeks are acceptable.

- **The Reports Step:** Calculate the remainder of the Personnel Planning Schedule and the Quarterly Personnel Summary. Generation of the demand by time period by crew type, the crew summary of Figure 4, would be done first. Extending the crew type out by the number of persons per crew would lead to person demand by week, termed the personnel summary. The Quarterly Personnel Summary would be generated from information located on the Personnel Projections Schedule. The personnel summary section would be an estimate of the number of personnel by classification by week (or quarter-month) required in the field office. The monthly average of personnel by classification could be calculated and added together for the office totals required on the Quarterly Personnel Summary.

**Operations Steps Summary**

Figure 8 illustrates the process required to create and maintain the Daily Personnel Assignments Schedule. The proposed system is expected to cover specific individuals in daily detail over short time periods. It must be flexible enough to allow constant adjustment of individual assignments as new information becomes available, while maintaining a slightly longer view on upcoming changes. This schedule is expected to be updated at least weekly, to maintain as high a level of accuracy as possible.

- **The Project Task Schedule Step:** Convert the project into crew related tasks and associate these with a daily calendar that covers a maximum time period of four weeks. Task duration would depend on a crew size or type change. Information required to do the task breakdown would include the project identification, the project plans, the add and/or construction start date and total project duration.
Figure 8. Flow Chart for the Daily Personnel Assignments Schedule
The Individual Assignments Step: Assign individuals by name to each defined project task. The information required for this matching would be a list of all members of the office staff and their classification levels, and the list of tasks and durations developed above. Determine at this time whether overtime or per diem would be required. The result would be a table with columns listing project tasks and rows listing individuals; entries at the junction of the columns and rows would indicate when the individual was assigned to a task.

The Schedule Step: Combine the information from the first two steps and create the proposed operations schedule with the daily task assignments for each person over the next four weeks as well as the project summary which outlines tasks and summarizes crew totals by task.

The Evaluation Step: Evaluate the schedule for whether all project tasks were adequately staffed and whether all personnel were committed at, or close to, 100 percent time throughout the period. If adjustments were not necessary, a usable schedule would exist; if adjustments were required, revisions would be made.

The Monitoring Step: Continue to collect the best information available on task start and end changes and personnel adjustments, ideally updating the schedule weekly. Two basic sources, the project inspector and the contractor, would be available for this information. Continue to evaluate the schedule for reasonable staffing levels and resource use.

Component Interactions

The planning and operations components of the system are expected to interact in two ways. First, the planning schedule could be used as the initial project task schedule for operations, refined as necessary to meet the detail requirements of operations. Second, current operations information on projects in progress would be periodically incorporated into the Personnel Projections Schedule. This process would be done at least quarterly and would result in easier scheduling methods and better foresight into potential scheduling problems.
APPLICATION:
SYSTEM DESIGN APPROACHES

THE MANUAL SYSTEM APPROACH

The manual implementation of these procedures would closely resemble the lists, tables and charts used in the conceptual system. Each of the reports, the Personnel Projections Schedule, the Quarterly Personnel Summary and the Daily Personnel Assignments Schedule, would become a form to fill in. Tables and charts, used to create the final reports, would also be fill-in forms. The steps would be done manually to process the information into the reports.

The only advantage to this approach would be that a standardized procedure for scheduling would be available. For field offices lacking formal scheduling capabilities, these procedures would result in documented personnel schedules. The major disadvantage is that it is time consuming to use, causing three system objectives to be compromised. Constant recalculation and redrawing would not encourage ease of use, the monitoring aspect, which would allow the system to minimize reactive management, would require swift responses and when creating a schedule becomes so time consuming, the effective use of personnel fails. Consequently, this system is not recommended for implementation except in limited circumstances.

THE SPREADSHEET SYSTEM APPROACH

Implementing the outlined system on a spreadsheet program is a reasonable alternative. All field offices currently have access to at least one spreadsheet program, LOTUS 1-2-3, which would allow the direct implementation of the proposed reports and procedures. The degree to which the overall system was automated could vary, depending upon the extent to which the designer wished to use various program capabilities. Planning and operations schedules would be completed separately in a spreadsheet system. Implementation of the schedules would closely parallel the procedures outlined earlier and would produce the final form of the reports as described.
Advantages include that

- many of the manual calculations would be removed from report production, offering flexibility;
- sections pertinent to each final report could be printed directly from the spreadsheet, with forms similar to the products described earlier; and
- the graphics extension capability would be used to visualize resource distribution.

The disadvantage would be the time required to set up this system. Each report section would need to allow for the addition and deletion of projects, project tasks and personnel, and recalculation of the summaries. Familiarity with spreadsheet programs and the macro programming language would be necessary for the designer to accomplish the task.

**THE NETWORK SYSTEM APPROACH**

The third approach, also a reasonable approach, would incorporate the use of network based project management software. Programs such as Microsoft PROJECT, which is supported by WSDOT, are thought to fit naturally into the context of any type of project management environment. Though they use a different method of input and report production, these programs still encompass scheduling and use of resources in a process much the same as the steps presented earlier in the description of the required system procedures.

Advantages to using a network program include that

- all calculations that are necessary to scheduling are already built in and no system development is required;
- updating is easy for both task start and end dates and classification/crew and individual resource files;
- master files with static information can be created; and
- planned schedules can be compared with actual schedules.

Disadvantages are that

- some time is required to understand completely the advantageous use of the program;
- the reports are not in the same format as the conceptual system has envisioned;
- the systems are based on traditional resource leveling methodology which is not applicable to the construction field offices;
- data for the Quarterly Personnel Summary are not able to be extracted automatically from at least Microsoft PROJECT; and
- operations schedules may be better used as interactive screens rather than constantly reprinted.
APPROACH ASSESSMENTS

Three approaches to implementing the personnel scheduling management system have been suggested. Though the manual system is not recommended for use in the construction field offices, it still might be useful. At least partial implementation of the manual form, perhaps simplified or in conjunction with some already in use, would help field offices that do not have any documented system. Adding features from the proposed manual system to existing manual systems also would make true schedules out of levels of scheduling that are missing certain essential elements.

The two computer-based systems each have different foci and strengths that could be advantageous to a field office, depending on the focus of the personnel scheduling system manager. It is also possible that a combination of the two computer based systems would work best for an office. The spreadsheet system is focused on the end products, the reports. The process is defined in terms of what the output should be like, and the system would be established to furnish the products. System design would be more difficult to do initially, but the end product would offer more flexibility, especially because the information could be presented in the proposed conceptual forms.

The network approach is focused on the process involved, the dynamics of the system. The system is already defined, and the user would employ the system to access the outputs that met the personnel scheduling needs. There would be less work in programming, but more in establishing the best way to access the system for the information required.

Both computer based systems would require some manual operations. The spreadsheet would require at least manual entry and updating of start and end dates and resource assignments, as well as initial spreadsheet set up information, which would be office-specific. Depending on the amount of automation through macros and cell formulae, more manual operations might be required. The network system would require that at least start dates and durations, task breakdowns and resources be manually entered. Once the network was operating, updating would be performed manually. The Quarterly Personnel Summary would also have to be extracted manually from data provided by the program or sent to the spreadsheet for automatic calculations.
