TRAFFIC SIGNAL LAYOUT AND CONDUCTOR TERMINATION

Presented By:
Keith Calais - HQ Traffic Office
Bob Hoover - HQ Traffic Office
INTERSECTION LAYOUT
STOP LINES
PEDESTRIAN CROSSINGS

• Make sure that everything needed to signalize the intersection is shown: pedestrian crossings, landings, ALL channelization, drainage, wetlands, utilities (above & below grade).
INTERSECTION LAYOUT - SERVICE AND CONTROLLER LOCATION

• Do not locate controller in wetland, ditch flow line or above buried utility.
• Make sure Maintenance has access, preferably access for vehicle also.
• Sight distance – try to locate controller on right side of minor leg.

MAST ARMS

VEHICLE AND PEDESTRIAN DISPLAYS

• Determine which phases are needed; which ones may be eliminated.
• Place signal heads, emergency pre-emption detectors, pedestrian signal heads & pedestrian push buttons.
• Do you need auxiliary push buttons for ADA? (Americans with Disabilities Act)
STANDARD LOOP NUMBERING

NOTES:
1. Ø 2 & 6 shall be oriented with the mainline. (Approach with higher volume.)
2. If SR runs N-S, Ø 2 shall be northbound.
3. If SR runs E-W, Ø 2 shall be eastbound.
4. Stop bar loops designated LXIA and LXIB shall have separate lead-in cables.
5. Stop bar loops designated LX2 shall be used in exclusive RT lanes.

LEGEND

LXXX  INDUCTION LOOP
→  VEHICLE DISPLAY
#  PEDESTRIAN DISPLAY
⊙  POLE NUMBER
• Layout Phases. Phase 2 shall be NB or EB in the overall direction of the SR layout.
• Mainline phases add up to 7, minor phases add up to 11.
- Label signal heads and signal standards.
• Label emergency preempt detectors.
• Label pedestrian signal heads and push buttons.
INTERSECTION LAYOUT

STOPLINE AND ADVANCE LOOPS

• Dilemma Zone detection for approach with posted speed at or above 35 mph. Design Manual (DM) section 850.06(6).
• At times, advance detection is placed on approaches with posted speed under 35 mph in the range of 100’ – 150’ back from the stop bar. This provides about 2 seconds of travel time.

• Loops are standard plan items.
• In most cases the stop bar loop is 3 loops wired together and brought back to controller on 1 each 2C(shielded). All other loops are brought back to controller on 1 each 2C(shielded).
INTERSECTION LAYOUT

JUNCTIONS BOXES AND CONDUIT RUNS

• Layout conduit- 2” diameter minimum on all legs. Use 3” diameter minimum for crossings.

• Layout conduit crossings - try to cross mainline only once. Try not to open cut mainline.

• Consolidate junction boxes around corners of intersection.

• Send the preliminary signal plan to HQ for review - per DM 850.06 (10), Page 850-14.
INTERSECTION LAYOUT

- Single pedestrian heads – 5C.
- Three section vehicle heads – 5C (except heads 21, 41, 61, 81 with permissive left turn).
- Five section vehicle heads – 7C.
- Double pedestrian heads on one shaft – 7C.
- Pedestrian push buttons and induction loops - 2C (shielded).
- Emergency pre-emption - 3C (shielded).

- Design a product for maintenance that they can maintain.
- Watch your conduit fill. Leave spares for future use.
- Run a 7C to heads 21, 41, 61 & 81 when running permissive left turns.
- Add tenons for future increased phase control.
- Send preliminary plan set to stakeholders for review.

Each Odd Phase Has 1 Count Register per phase.
Each Even Phase Has 2 Count Registers per phase.
WAPITI 170 VEHICLE DETECTION OPTIONS

- The vehicle detector term “Extend” (E) means that the loop detector will output to the controller during the green display. The term Call (C) means that the loop detector outputs to the controller during the yellow and red displays.

**ODD PHASES (1, 3, 5, 7)**

- Typically stop line detection Extension, Call (E, C) operation.
- Odd phases are generally left turn phases.
- There are three channels of vehicle detection for “Odd” phases.
- For phase 1 input file “I” slot No. 1 upper and lower channels and the upper channel of slot 9.
- For phase 3 input file “I” slot No. 5 upper and lower channels and the lower channel of slot 9.
- “Odd” (1, 3, 5, 7) phases have one count register each.
- Phases 5, 7, in the “J” FILE, operate identically to phases 1, 3.

**OTHER DETECTION OPTIONS**

- Delay - This option builds a time delay into the controller until the programmed time have elapsed, the delay is canceled during phase green.
- Carryover(stretch) - This option extends the detection by a programmed number of seconds during phase green.
- The extend, call operation is the same for even phases as for ODD phases.
• “EVEN” PHASES (2, 4, 6, 8)

• One of the options is programming either phases 2 & 6 or phases 4 & 8 even phases. It is possible to only operate a single phase to add additional time to the programmed minimum initial time, but this is not a practical type of operation. The stop line detection loops are connected to the Call (C) only positions. When this option is selected it is generally applied to the main street through phases, typically phases 2 & 6, or occasionally phases 4 & 8, if these are the main street phases.

• This operation adds time to the minimum initial timer, in settable increments of 1 to 3 seconds per increment.

• The desired goal is to add sufficient time to clear the queue that develops during yellow and red intervals of main street. It is important to set a maximum amount of added initial time, a failed detector could add 15 minutes to the minimum initial.

• The goal here is to clear the queue and achieve free flow traffic, with the green extended only by the advance detectors. This operation is difficult to achieve due to varying driver behavior.
• MORE OPTIONS FOR “EVEN” PHASES (2, 4, 6, 8)
• A second “Even” phase option is called TYPE detection. As in the above option the stop line loops are connected to the Call (C) positions. The following must be entered (programmed) into the controller (for phase 2, D+4+6, for phase 6, D+5+6, for phase 4, D+4+D, for phase 8, D+5+D.

• Normally only phases 2 & 6 or 4 & 8 will be programmed, not all “Even” phases. This programming will program the controller to use the stop line detection until there is an instant of time where there is no vehicle detecting the controller. At that instant the phase that this occurs on will no longer have stop line extension, the other “even phase will continue to operate until there is an instant where there is no vehicle detecting the controller present.

NEMA Controller

MANUFACTURER PROVIDED SOFTWARE
MANUFACTURER DRIVEN SPECIFICATION
NEMA input files have additional connections to each loop detector. These connections make the following additional functions available:

- Detection stretch (extends call after vehicle leaves loops), delays waits a programmed amount of time before outputting call to controller.
- Red / green detection inhibit (inhibits call during red or green assigned phase).

Traffic Signal Timing Terms
• Minimum green - Is the first timed portion of the green interval, and is timed concurrently with passage timer and the maximum timer. The guaranteed minimum green time for the phase will be the greater of either minimum or passage time.

• Passage time – The maximum amount of time set between detector actuations, while in a green condition to not cause a gap out. Passage starts timing at beginning of green unless sequential timing is active.
• **Maximum 1** - Determines the amount of time that the phase will be green, with the presence of an opposing call. The timer starts at the beginning of the green interval. If there is no opposing call, it will not start timing. Exception: pedestrian time will override maximum time setting.

• **Maximum 2** – Will be used in place of maximum 1 when selected. Maximum 2 may be selected manually or by time clock.
• **Walk** - The time period of time controls the amount of that the “WALK” is displayed.

• **Flashing Don’t Walk** - This is pedestrian clearance time interval. It is calculated by measuring from the curb to the center of the furthest traveled lane, before opposing vehicles receive a green indication. The measured distance is then divided by 3.5 or 4 (walking speed in feet per second).
Yellow clearance - The amount of time a movement will be in the yellow condition.

Red clearance - Establishes the length of the red clearance interval following the yellow clearance interval. Generally considered to be equal (in seconds) to the width of the intersection (in feet) divided by the approach speed in feet per second.
Fiber Optic Interconnect

Cat 5 (RJ-45) To 2070 traffic signal controller.

This is the Fiber optic patch panel – with 6 fibers or 12 fibers.

One Ethernet switch needed at each traffic signal.

Fiber port for future camera operations at traffic signal.

From 24 volt power supply.

120 VAC from power distribution assembly.

Use only one for each corridor of traffic signals (talk to ITS group).

these 2 fiber optic patch cables terminate at the patch panel above.

Cat 5 (RJ-45) To 2070 traffic signal controller.
Ethernet switch
