16. ABSTRACT

This report presents and summarizes the data collected in fulfillment of the requirements for the Washington State Department of Transportation grant "HOV Lane Evaluation and Monitoring." This report provides the information necessary to analyze HOV lane performance and development. Data collection results and analysis are presented, followed by conclusions and recommendations.

The data contained herein were collected during Phase I, Phase II, Phase III, and Phase IV of the high occupancy vehicle lane (HOV) monitoring project (July 1992-June 1998). The data collection methodology is described in the final report, "HOV Monitoring and Evaluation Tool." Included in this report are the following primary and secondary measures of HOV lane performance: (1) average vehicle occupancy data, (2) travel time data, (3) public opinion survey results, (4) transit ridership data, (5) enforcement, compliance, and adjudication data, and (6) accident data. Data collection issues and their implications for data availability are discussed.

It is important to note that this report does not evaluate the HOV lane system in the Puget Sound region. Rather, it is a compilation of the data necessary to conduct a meaningful evaluation. Although an analysis of public opinion, transit ridership, and enforcement data is provided, the report's primary purpose is to simply present the data and discuss issues associated with its use,-not to provide an extensive analysis.

This report does not constitute a standard, specification, or regulation.

TABLE OF CONTENTS

HOV LANE EVALUATION AND MONITORING

ABSTRACT

This report updates the previous report with the same title dated August 1997 (WA-RD 414.2) and summarizes the data collected in fulfillment of the requirements for the Washington State Department of Transportation's contract HOV Lane Evaluation and Monitoring. This report provides the information necessary to analyze HOV lane performance and development. Data collection results and analysis are presented, followed by conclusions and recommendations.

The data contained herein were collected during various phases of the high occupancy vehicle lane (HOV) monitoring project (July 1992-June 1998). The data collection methodology is described in detail in the companion report, *HOV Monitoring and Evaluation Tool.* (1) Discussed in this report are the following primary and secondary measures of HOV lane performance: (1) vehicle occupancy data; (2) travel time data; (3) public opinion survey results; (4) transit ridership; and (5) enforcement, compliance, and adjudication data. Additional secondary measures such as transit load factors and HOV lane accident rates can be obtained by contacting Metro, Community, and Pierce Transits and the Washington State Patrol, respectively. Data collection issues and their implications for data availability are also covered.

It is important to note that this report does not evaluate the HOV lane system in the Puget Sound region. Rather, it is a compilation of the data necessary to conduct a meaningful evaluation. Although an analysis of public opinion and enforcement is provided, the report's primary purpose is to simply present the data and discuss issues associated with their use, not to provide an extensive analysis.

EXECUTIVE SUMMARY

This is the fifth in a series of annual data reports for the High Occupancy Vehicle Lane (HOV) Monitoring and Evaluation project, sponsored by the Washington State Department of Transportation (WSDOT) and the Federal Highway Administration (FHWA). The purpose of this project is to collect data on the usage of the HOV lane system in the Puget Sound region and to make those data available to a wide audience of transportation planners and authorities. Completion of the HOV lane system is a high priority for WSDOT. However, it is useful to understand the strengths and weaknesses of the current HOV lane system before the significant costs of constructing new HOV lanes are incurred. The companion report, *HOV Monitoring and Evaluation Tool* (1), describes the data collection methodology in detail and is supplemented with quarterly reports covering any changes to collection measures.

This report is not an evaluation of the HOV lane system in the Puget Sound region; rather, it is a compilation of the data necessary to conduct a meaningful evaluation. However, some of the data included in this report will need to be studied more closely before substantive recommendations on existing HOV lane policy can be made. Data are primarily presented in raw form; interpretation and relationships to other data are provided when appropriate. The key elements of this data collection effort are, (1) it gathers a wide range of information about the HOV lane system from throughout the Puget Sound region and (2) the collection effort is sustained over time. These elements will allow WSDOT planners to assess the changes in travel behavior that an HOV lane system is designed to induce, particularly where HOV lanes do not currently exist.

Analysis of the types of data outlined below will enable WSDOT to evaluate the performance of the HOV lane system in terms of the objectives described in the 1992 Washington State Freeway HOV System Policy report. HOV systems serve the following objectives:

- *Improve the capability of congested freeway corridors to move more people by increasing the number of people per vehicle.*
- *Provide travel time savings and a more reliable trip time to high occupancy vehicles that use the facilities.*
- *Provide safe travel options for high occupancy vehicles without unduly affecting the safety of freeway general-purpose mainlines.*

Measures of effectiveness used to determine the impact of the HOV system include the following:

- *person throughput*
- *vehicle occupancy*
- *comparative and absolute general-purpose (GP) and HOV lane travel times*
- *travel time reliability.*

Data collection since August 1996 has centered on both travel time savings and average car occupancy (ACO) analysis at the request of WSDOT. In general, the HOV system has performed as expected. Most problems have occurred in the commute direction along the start or terminus of a given HOV lane, at major freeway intersections, and through the central business districts (CBDs) within Puget Sound. Results of the AVO data are in Appendix B, with corridor descriptions given in Chapter 2. Results for the high occupancy vehicle travel time (HOVTT) data are in Appendix F and G, with corridor speed evaluations given in Chapter 4.

Overall, the support for HOV lanes continues to remain high among all commuters, but opinions of HOV drivers and SOV drivers are diverging on issues related to HOV lane usage, performance, and funding. Fortunately, the public's support is as strong as ever when it comes to continuing with construction of the HOV system, with 71 percent of survey respondents in favor of the idea. In response to what options may help

improve the current HOV system, the public supports issues related to expansion and enforcement over issues linked to transportation management such as employer subsidies, increased bus service, and more Park & Ride lots.

The period covered by this report was July 1992 through June 1998. The data were collected under the methodology developed for the HOV Monitoring and Evaluation Tool project, with changes in collection methodology noted in the supplemental quarterly reports. The collection of conventional travel time data was suspended as of July 1993, but it resumed in October 1995 utilizing the HOV Travel Time Floating Car Method [HOVTT (fcm)]. Violation information was provided by the HERO program (see Chapter 6), the Washington State Patrol Violation Recap Agency, and the Office of the Administrator for the Courts. Data on vehicle occupancy and travel time (two methods) are presented in Appendices B, E, F, and G. The ACO data and HOVTT data will be updated quarterly and made available via the Internet at http://www.wsdot.wa.gov/eesc/atb/atb/hov/Titlepg.html.

Recommendations

The following recommendations are guidelines for the continued success of the project. Although they are presented here as brief statements, a further explanation of their importance is provided in Chapter 7 of this report.

1. Continue to prioritize observations at locations that ensure the best use of resources.
2. Evaluate the appropriateness of collecting vehicle occupancy data on the I-5 express lanes.
3. Use short travel time study sections.
4. Conduct more travel time data collection sessions per study section.
5. As a special study, conduct travel time observations of the express lanes.
6 Conduct periodic reviews of the survey to ensure the appropriateness of its content.
7. Conduct a special study of repeat offenders to shed some light on the extent to which violators change their behavior after receiving a ticket.
8. Conduct a special study on highway corridors characterized by chronic violation problems.
9. Index funding for data collection efforts with the opening of new HOV lane miles.

CHAPTER ONE: INTRODUCTION AND RESEARCH APPROACH

PURPOSE AND PRODUCTS

The purpose of this project is to provide a comprehensive set of data for the HOV lane system in the Puget Sound area. These data will be primarily used by transportation planners and authorities to evaluate the performance of the HOV lane system and to aid planning of other HOV facilities. This report is the fifth in a series of annual data reports that will allow parties to track changes in the performance of the HOV lane system over time. This report also contains recommendations for future HOV lane policy and evaluation efforts. Information concerning the data collection method is available in the companion report, *HOV Monitoring and Evaluation Tool* (1). Periodic changes in methodology are noted in subsequent quarterly reports that are available locally.

MEASURES OF EFFECTIVENESS

HOV lanes are intended to reduce average travel time and to increase travel time reliability for transit users, carpoolers, and other ridesharers. HOV lanes are supposed to provide a relatively unobstructed lane for users. For these reasons, HOV lanes are expected to encourage transit use. The expected reductions in both travel time and congestion must be measured to determine whether HOV lanes are cost effective. Vehicle occupancy, travel time, and public opinion are the three types of primary data collected by this project. Secondary sources are used to assess enforcement and violations along HOV lanes. Although traffic volumes and person throughput may be estimated from vehicle occupancy data, it is not the intent of this report to estimate these or any other categories, such as violation rates, as related to traffic flows. Traffic volumes are better measured using volume data from inductance loop detectors; person throughput can then be estimated by multiplying the volume data by occupancy data

percentages. Analysis of violation rates also depends on the availability of traffic volume data. Inductance loop data are not currently collected as a part of this project, but this information can be obtained by contacting WSDOT Northwest Region. The data collection efforts have focused on the following measures:

- **Vehicle Occupancy/Mode Choice.** Vehicle occupancy is recorded by human observers in the field at 53 sites in the Puget Sound area. Data are collected from HOV lanes, general purpose lanes, and access/egress ramps to provide a profile of commute patterns, congestion, and the average number of passengers traveling along commute routes during peak commute hours. Now that the project has a solid baseline of occupancy counts at a variety of site locations, observation sessions are scheduled exclusively at mainline sites within the Puget Sound region. Rather than average vehicle occupancy (AVO), average car occupancy (ACO) is derived from the data.

  Determining AVO requires the use of transit and vanpool loading factors specific to the region under consideration (Chapter 2). Ridership information can be obtained from the three local transit agencies that operate routes on HOV lanes: Metro (King County Department of Metropolitan Services), Community Transit (Snohomish County), and Pierce Transit (Pierce County). These data should focus on changes in ridership over time for routes along freeway segments that contain HOV lanes.

  Mode choice data can be derived from vehicle occupancy and are supplemented by survey results from this project. Subsequent sections of this report discuss data collection and the implications these methods have on the data available. A regression analysis of the baseline vehicle occupancy data was performed in 1993, and those results are discussed further in Chapter 2.

- **HOV Violations.** Violation rates may be calculated for peak-hour commute times by determining the number of single occupant vehicles (SOVs) that use the HOV lane. Data from ACO observations, the number of HOV violation tickets and warnings issued by the Washington State Patrol (WSP), adjudication results, and information from the HERO program indicate the frequency of HOV violations and the enforceability of current restrictions (see Chapter). Taken together, these sources provide information about reports from citizens on HOV violations on area highways, tickets and warnings issued primarily by law enforcement officers, and the number of paid tickets and the outcomes of contested tickets in the courts. Survey results provide information about regional commuters' perceptions of violations.

- **Safety.** Public opinion survey results provide information about commuter perceptions of HOV lane safety. These data measure the level of concern about safety and its impact on mode choice.

- **Travel Time.** Travel time data measure the effectiveness of HOV lanes at reducing commute times and improving reliability. Originally, a license plate matching method was used to measure and compare travel times on HOV lanes and general purpose lanes. Multiple counts at specific sites and roadway segments measured the travel time reliability function of HOV lanes and estimated the speed and flow of traffic. Over time, renewed observations may be used to measure the absolute and relative travel time savings for HOV lanes. Because of the demands on resources this method exacts and the level of labor required to produce significant samples, a different method of a data collection was adopted in October 1995: the Floating Car Method (fcm). Observers collect actual travel time data during the commute period by measuring the time differentials between given roadside landmarks. This method is further described in Chapter 4.

- **Public Opinion.** Public opinion data indicate the HOV program's perceived importance and effectiveness, as well as ways it may be modified to appeal to more of the region's drivers. Public opinion is measured by analyzing survey results from randomly selected commuters observed along freeway routes that contain HOV lanes during peak commute periods. Mail-out surveys were sent to drivers of both HOV and SOV vehicles identified in the field by traffic observers. The mail-out surveys were designed to elicit area drivers' perceptions of the attractiveness, efficacy, safety, and violations of HOV lanes. This report presents public opinion data to show overall results and to determine differences in opinion between ridesharers and SOV commuters.

These measures of effectiveness categories provide a valid basis for evaluating the performance of the current HOV lane system. They also help address WSDOT's information needs for determining where and when to construct new HOV facilities. WSDOT's *HOV Lane Minimum Threshold Policy* states four preconditions for HOV lane construction:

1. facility demand exceeds capacity for more than one hour each day
2. evidence exists that an HOV lane will move more people per hour during peak periods than the per-lane average of the adjacent general purpose lanes
3. there is local support for HOV lane construction
4. The HOV lane segment will improve continuity by linking other HOV lane corridors identified in the *Year 2000 HOV Core Lane System* (3).

The ACO and public perception data available from this study will provide WSDOT with some of the information necessary to evaluate minimum threshold requirements for new HOV lane construction. These data will also be useful in decisions

concerning lane configuration, occupancy requirement policies, and general purpose lane conversion.

The data published in this report will be readily available to WSDOT officials and planners, as well as to other interested jurisdictions. Analysis of much of the data requires specialized computer programs designed for this project, in addition to the Statistical Package for Social Sciences for Windows (SPSSWIN) statistical analysis program.

DATA COLLECTION

As stated before, extensive documentation of the data collection method used for this project is provided in the companion report *HOV Monitoring and Evaluation Tool* (1) and in supplemental quarterly reports. However, a brief explanation of the data collection process is in order.

This study employs human observers to collect data pertaining to vehicle occupancy and travel time, as well as the information necessary to send out public opinion surveys. Traffic observers count the occupants in each vehicle in a given lane as the vehicle passes beneath a highway overpass or through an access ramp. Travel time data have been collected by matching license plate numbers with unique time indices at two points along a roadway. Current travel times are collected by means of the Floating Car Method. Observers drive the HOV lanes (and sometimes the general purpose lanes) during the commute period and measure the time differential between given roadside landmarks. Observers also collect license plate numbers of both HOVs and SOVs to generate comparable samples for the public opinion survey. These observers enter data onto personal computers (observers originally used Toshiba T1000 laptops but now use smaller, more reliable Hewlett-Packard HP-95 palmtop computers) and hard-copy forms when necessary. Data are collected on the major interstate and state highways in the region: I-5, I-90, I-405, SR 520, SR 16, SR 167, SR 410, and SR 512 between the peak

commute hours of 6:00 AM to 9:00 AM, and 3:00 PM to 6:00 PM (three hours each). State highways 16, 167, 410, and 512 were added to this list in the third quarter of 1993, but SR 167 is the only one of these routes currently under observation. No data regarding express lane traffic on the I-5 north and I-5 downtown corridors have been collected, but AVO data on the reversible lanes of I-90 have been available since the third quarter of 1994. At the same time, for ease of data management and to increase the number of data collection sites, the I-405 corridor was divided into three corridors: I-405 South, I-405 Central, and I-405 North (1). Observation sites were also added to I-5 in Everett and Tacoma. ACO data from July 1995 to the present are available for all mainline sites. Table 1.1 indicates the type of data collected, the data collection quarters, and their corresponding dates for this study. (See Table A1 for the beginning dates of study for the data collection sites.)

Table 1.1: Data Collection Period, by Quarter

Type	Quarter of Study	Dates
AVO	Q3/92	July 3, 1992 - October 2, 1992
AVO	Q4/92	October 5, 1992 - January 1, 1993
AVO	Q1/93	January 4, 1993 - April 2, 1993

HOVTT	Q1/98	January 2, 1998 - March 27, 1998
AVO	Q2/98	March 30, 1998 - June 26, 1998

The type of observation performed and the collection method used affect the success of occupancy and travel time data collection. The objective is to conduct as many observations for a wide distribution of sites, with a goal of ten half-hour counts per type of lane (GP vs. HOV) per quarter per site for ACO data collection. To make the best use of resources, data collection has focused on the direction in which peak period traffic is expected to flow. The type of data being gathered, the number of observers, logistical considerations, and the success of previous observations affect scheduling. Data collection is further affected by such factors such as the site's geographic characteristics, weather and light conditions, observer performance, and data quality management.

The occupancy and travel time data presented in this report are from 59 sites studied during the first three phases of data collection (38 sites are for occupancy, 8 are for travel time data collection, and 13 are used for both). Only ACO data and data using the floating car method [HOVTT (fcm)] are now being collected. Baseline travel time data collection using the license plate method was discontinued as of July 1993 (1).

REPORT ORGANIZATION

Chapter 2 discusses vehicle occupancy data. Chapter 3 analyzes these ACO data. Chapter 4 discusses travel time data. Chapter 5 provides comprehensive information from the public opinion survey. Secondary data sources pertaining to enforcement, compliance, and adjudication are presented in Chapter 6 with project conclusions and recommendations contained in Chapter 7. The appendices contain vehicle occupancy and travel time data, as well as relevant supplemental information.

CHAPTER TWO: BASELINE VEHICLE OCCUPANCY DATA

Vehicle occupancy data are an empirical measure of commuter mode choice. This measure can also be used to evaluate the effect of HOV lanes on the person-carrying capacity of commute corridors. Vehicle occupancy data indicate the proportion of vehicles of a certain occupancy or mode at a given freeway location during the weekday peak commute. For the project's ongoing collection, observers record the vehicle occupancy and mode at mainline and ramp locations by using a program that time-stamps each observation. Average car occupancy (ACO) is then calculated from these observations with the formula shown in Figure 2.1. Note that only passenger vehicles are considered in the calculation of this number. To calculate average vehicle occupancy (AVO), the formula in Figure 2.2 is recommended, but with reservations. The weighting factors of 10 and 40 occupants (for vanpools and public transit buses, respectively) vary by site, time of day, direction of travel, and quarter, and are likely to overestimate AVO. For this reason, ACO, rather than AVO, is used in the remainder of this report. AVO can only be estimated after the average vanpool and bus loadings for each location have been acquired from the appropriate transit agencies.

Average car occupancy (ACO) can be calculated using the following formula:

$$ACO = \frac{(1 \times SOV) + (2 \times DOV) + (3 \times TOV) + (4.1 \times FOV)}{SOV + DOV + TOV + FOV}$$

where

- ***SOV*** is the number of single-occupancy vehicles observed
- ***DOV*** is the number of double-occupancy vehicles observed
- ***TOV*** is the number of triple-occupancy vehicles observed
- ***FOV*** is the number of vehicles observed with four or more occupants.

Note: Vanpools, buses, other transit vehicles, motorcycles, and tractor semi-trailers are not considered.

Figure 2.1: Calculation of Average Car Occupancy

Average vehicle occupancy (AVO) can be calculated using the following formula:

$$AVO = \frac{(1 \times SOV) + (2 \times DOV) + (3 \times TOV) + (4.1 \times FOV) + (\underline{10} \times VAN) + (\underline{40} \times PT)}{SOV + DOV + TOV + FOV + VAN + PT}$$

where

- ***SOV*** is the number of single-occupancy vehicles observed
- ***DOV*** is the number of double-occupancy vehicles observed
- ***TOV*** is the number of triple-occupancy vehicles observed
- ***FOV*** is the number of vehicles observed with four or more occupants
- ***VAN*** is the number of vanpools
- ***PT*** is the number of public transit buses.

Note: Other transit vehicles, motorcycles, and tractor semi-trailers are not considered.

Figure 2.2: Calculation of Average Vehicle Occupancy

Occupancy data in this report are presented in Appendix B according to the following characteristics:

- corridor of study
- observation site
- AM or PM peak period
- traffic flow direction
- mainline (GP or HOV) or access/egress ramp location.

Data indicate the number of vehicles that were observed by type of occupancy, the total number of vehicles, the ACO, and the number of counts successfully conducted for each quarter of the study. Data about mainline locations include the number of lanes so that the average counts per lane can be estimated for comparing general purpose (GP) lanes with HOV lane data. The figures in these tables are work-week and commute period aggregates (thereby assuming that the daily ACO does not vary significantly).

Although the data may be disaggregated by day of the week, by hour of commute, or by lane of traffic if desired, at some locations a sufficient number of observation

sessions may not have been completed to make this possible. Occupancy data may also be aggregated to determine the overall ACO for the following:

- multiple sites of a corridor
- combined GP and HOV lanes
- all access/egress ramps
- simultaneous directions of traffic flow (within the limits of the data and aggregation program).

Because loop inductance data gathered from these sites are more representative of corridor traffic volumes, the data presented herein should only be used to generate estimates of the distribution of vehicle mode and occupancy (e.g., proportions of SOVs). Occupancy data presented in this report should *not* be used to compute traffic volumes.

During Phase I of this project, vehicle occupancy data were collected from 41 sites. Each had either mainline or access ramp locations, or a combination thereof, amounting to 14 mainline and 26 access/egress ramp locations. During Phase II, data collection was expanded to include sites in Tacoma, Everett, and Issaquah for a total of 53 sites with 10 new mainline and two access/egress ramp locations. ACO data collection during Phase III was severely limited because of budget constraints, with the number of sites reduced by roughly a third. The data, shown in Appendix B, are available beginning with the third quarter of 1992 and ending with the second quarter of 1998 (see Table 1.1 for the quarters and their calendar equivalents). In Appendix B, the data for each site are preceded by a diagram denoting the locations of sites within a given corridor, followed by a lane diagram of the site that indicates the traffic flow direction and type (mainline or ramp). Comments made by observers while they were collecting occupancy data can be found in Appendix C. These comments pertain to the weather and traffic conditions in which the data were collected.

OCCUPANCY DATA AVAILABILITY

A minimum of ten 30-minute counts per type of lane per quarter per site for each peak commute period are necessary to provide statistically significant data (2). Under optimum conditions, five to six counts are conducted per 3-hour session. Although collection was designed with this requirement in mind, the significance of results is affected by the availability of the data collected, as well as by the variation of each site's peak period. The availability of data for these sites depends on the number of observation sessions scheduled and on the number of counts successfully performed for a given quarter. (For a description of factors likely to render data unusable, please refer to *HOV Monitoring and Evaluation Tool.*) These conditions are affected, in turn, by a number of factors, including the direction of traffic flow, the weather, geographic characteristics of the site location, and the success of scheduling efforts. Because of the large number of locations involved, counts have been prioritized in favor of sites that are expected to capture more typical traffic patterns. Additional locations have been scouted and scheduled as the project has progressed. Scheduling is also affected by the availability of transportation for observers.

Because of these variables, data for some tables are incomplete. In the majority of cases in which data are insufficient, it is because no counts had been scheduled during that time. In other cases, only one or two counts were completed, and the available data files were not usable (see *HOV Monitoring and Evaluation Tool* for a discussion of causes (1)). In addition, data may be unavailable for specific lanes of traffic at certain mainline locations because the number of lanes exceed the number of counts conducted at those sites.

Scheduling

Determining which sites to use is a process that has developed over time, partially as a result of learning which locations are better for observations, as well in response to

WSDOT requests for new information. During the first two quarters of data collection, emphasis was placed on scheduling observations according to expected commute patterns: e.g., inbound Seattle central business district (CBD) traffic during the morning commute and outbound traffic during the evening commute. In areas where this pattern was less clear, such as the CBD traffic on the downtown I-5 corridor and the suburb-to-suburb traffic on the I-405 corridor, collection efforts were expanded to include less obvious reverse traffic flows as well. Although most sites had been identified by the summer of 1992, months of observation were needed to discern these counter-traffic patterns and to schedule observations accordingly. Scheduling success is also affected by whether student observers have transportation; because more than one observer typically relies on a single vehicle, if that vehicle is not available, the counts for the affected observers are canceled. Whenever possible, canceled observations are rescheduled.

Visibility

The ability to see into passing vehicles--and thus to observe the number of occupants accurately--is affected by the positions of the observer, the traffic, and the light source (1). Because visibility can be greatly affected by weather conditions, the usefulness of sites typically remains unknown until the weather and light conditions change. Overpasses are generally undesirable because the farther away an observer sits from traffic, the more difficult it is to see into passing vehicles. However, overpasses do provide the best combination of visibility and safety in comparison to street level sites, which do not allow observers to see all lanes of traffic. As weather and light availability changes, a site on an overpass that provides a good view into the interiors of vehicles in the summer may become useless in the winter because streetlights are absent or provide insufficient light to see into passing vehicles. Under such circumstances, data collection may be limited to daylight hours. The result is that, for a number of locations, data during the fall and winter quarters (e.g., Q4/92 and Q1/93, respectively) are not available.

Darkness during the winter months has forced morning counts to begin after 7:30 AM and evening counts to end before 5:00 PM--an hour to an hour-and-a-half later (or earlier) than scheduled. Therefore, instead of the expected five to six counts per session, only three to four counts per session may have been successfully performed during the fall and winter quarters, if at all. Now that baseline data collection for most of the data sites has been completed, ACO observation will be conducted during the lighter spring and summer months, whereas HOVTT data will be collected during the darker fall and winter months. Another issue that affects observer performance is whether traffic is approaching or going away from observers. (4)

Mainline Observations

Mainline data include both HOV and GP observations; these are collected by observing a different lane for each 30-minute count. Ramp data are collected by observing the same ramp throughout the session. The number of lanes at each mainline location is shown in the site diagram and displayed under the location heading ("GP lanes" or "HOV lanes") (see Appendix B). Although the observers collect data separately for each individual lane, the analysis program distinguishes only between HOV and GP lanes (thereby combining the data for individual GP lanes). As a result, the number of counts performed for GP lanes effectively outnumbers those for HOV lanes, which makes a direct comparison between the two types of lanes difficult.

In an effort to make the samples of HOV and GP lanes more comparable, a type of rotation counting was adopted in the fourth quarter of 1994. Observers now begin their sessions with the HOV lane, proceed to a GP lane for their second count, and then return to observing the HOV lane for their next count. By repeating this order, sample sizes of HOV and GP lanes will be fairly uniform for each quarter. For ACO data collected before Q4/94, the number of HOV and GP lanes must be taken into consideration to compare HOV lane with GP lane observations. This can be done by

dividing the number of quarterly counts by the number of each type of lane to obtain the average number of counts per lane.

Data availability for mainline locations is affected by a number of factors. Although mainline data are preferable to data collected at access/egress ramps, they are more difficult to obtain. They require the use of overpasses, which are more difficult to locate because overpasses occur less frequently than access/egress ramps, and those with characteristics favorable for observing vehicles (such as adequate lighting and lower height (1)) are even rarer. In the past, observations were scheduled to obtain mainline data from at least one overpass per corridor and access ramp data were collected to supplement the data during the winter months. As a result, data tend to be more readily available from ramp locations during the winter months. Currently, ACO observations are suspended between October and April each year in favor of HOVTT travel time data collection.

Data also may be unavailable for individual lanes of certain mainline locations because the number of lanes is greater than the number of possible counts per session. During a three-hour session, observers are able to conduct up to six half-hour counts. When observers are faced with more lanes of traffic than the conditions of the session allow, at least one lane may be missed for any given session; during the fall and winter quarters, this number rises to include at least two lanes. This limitation has been counteracted by specifying the lane at which a session is to begin and then rotating the order of the lanes so that each lane will be observed at least once per quarter.

Ramp Observations

There are almost twice as many ramp sites as there are mainline sites. Because access/egress ramps are more numerous and typically have better lighting than overpasses, they were ideal locations for observing vehicle occupancy. An important feature of access/egress ramps (particularly on-ramps) is that data were likely to vary

greatly. This is due to the lower volume of vehicles they carry, which means that there was a greater chance for random variation. Ramp locations were therefore studied to supplement mainline data, as well as to determine whether some of their data could be used as "proxies" for data gathered on the mainlines. A result is that some locations were only counted during the winter months. Both on- and off-ramps were used. In places where ramps had metered GP and HOV bypass lanes, vehicles were recorded regardless of the lane, thereby combining the data for these locations. Ramp observations were discontinued at the end of the second quarter of 1995 because of budget cuts, and no plans to renew collection efforts are under consideration.

AVERAGE CAR OCCUPANCY SITES

I-5 North Corridor

The I-5 North corridor is 9.4 kilometers long, beginning at NE Northgate Way (north of SR 520) and continuing to 236th Street SW. Four evenly spaced sites have been used with well-lighted locations: 236th Avenue SW, N 175th Street, N 145th Street, and NE Northgate Way. For all sites, morning southbound and evening northbound traffic has been measured from on- and off- ramp locations, respectively. Of these, only N 145th Street has been used for mainline data collection. Data are unavailable for 236th Street SW for the AM northbound flows during the second quarter of 1993 (Q2/93) and for the PM southbound flows during the third and fourth quarters of 1993. No data have been collected for 236th Street SW, N 175th Street, or any ramp observation sites since Q2/95.

I-5 Downtown Corridor

This corridor begins at S 144th Street and ends at Roanoke Street, a distance of 18.9 kilometers, including I-90 and ending at the I-5/SR 520 interchange. Conducting observations in this corridor has been difficult because both directions of traffic have to be examined for each commute period (there is no obvious directional flow). Additionally, because of the irregular layout of the access/egress ramps, it is impossible to conduct observations in the same manner as is possible at suburban locations with traditional cloverleaf or diamond patterns. Because no single set of locations can satisfy collection requirements, a greater number of sites have to be used. Six ACO sites--Lakeview Boulevard E , Roanoke Street, S Holgate Street, Albro Place, Madison Street, and S 144th Street--have been used for mainline observations. Eight sites--Lakeview Boulevard E, Corson Avenue S, Stewart Street, S Michigan Street, Olive Street, Madison Street, and Howell/Yale Sts.--have been used for ramp data collection.

The majority of observations have been conducted around three clusters of ramps: one set north of the downtown central business district (CBD), a second set at the CBD, and third set south of the CBD. *North of the CBD*, observations were conducted at Lakeview Boulevard E, but the site was then replaced by Roanoke Street (which was found to be better because it was closer to street level) during the first quarter of 1993 (Q1/93). However, observations at Roanoke were discontinued Q3/95.

Within the CBD, locations at Olive Way (northbound, evening on-ramp) and Howell/Yale Sts. (southbound, evening on-ramp) have provided for "outbound" traffic; Madison (northbound, morning off-ramp) and Stewart Street (southbound, morning off-ramp) have provided for "inbound" traffic data. Morning counts at Olive Street and Howell/Yale Sts., northbound, did not begin until later in 1992. Mainline data collection at Madison Street was a special study begun at the request of WSDOT District 1 during the Q2/93. Ramp data collection began in the fourth quarter of 1992 (Q4/92) for AM counts and in the fourth quarter of 1993 (Q4/93) for PM counts. Stewart Street was not added until Q4/92 for AM counts and until Q4/93 for PM counts. Data are unavailable for Olive Way AM counts during Q3/93, Howell/Yale Sts. counts AM during Q3/93, and Madison AM counts during Q4/93 because observations were not scheduled. Currently no observations are being conducted along this section of I-5 within the CBD.

South of the CBD, counting at S Holgate Street was changed to counting at Albro Place because of the unfavorable characteristics of the site. (There was a sidewalk on only one side of the overpass, and at the time, the HOV lane ended about 200 yards before the overpass, making it difficult to determine vehicle occupancies in that lane.) Observations were suspended at the following sites: S Holgate Street and Corson Avenue S, beginning Q1/93, S Michigan Street, beginning Q2/93, and mainline evening counts at S 144th. St., beginning Q1/93. Site #25 (Albro Place) is the only location where ACO data have been collected along this corridor since Q2/95.

I-5 South Corridor

The corridor begins south of the I-405 interchange, at S 188th Street, and continues south to S 272nd Street, for a distance of 8.9 kilometers. Data collected during the morning commutes have been for northbound traffic (on-ramps only); afternoon data have been collected from only southbound traffic (off-ramps only). Of the seven occupancy collection sites, one (S 216th Street) has been used exclusively for mainline observations; the remainder (S 188th Street, S 200th Street, SR 516--Kent/DesMoines Road, SR 516--Kent ramp, SR 516--DesMoines ramp, and S 272nd Street) have been used to collect ramp data. The ramp locations at SR 516 have been treated as if they were three different sites.

An instance of observations missing where sessions were conducted is the HOV lane of S 216th Street in the morning northbound lanes (Q4/92). The data from the two counts completed for that lane were found to be unusable. No observations were scheduled at the SR 516--DesMoines on-ramp AM northbound for Q2/93, the S 188th St. off-ramp PM southbound for Q2/94, and the S 272nd St. on-ramp AM northbound for Q1/94 and off-ramp PM southbound for Q4/93. Site #34 (S. 216th St.) is the only location where ACO data have been collected along this corridor since Q2/95.

SR 520 Corridor

This corridor is 7.9 kilometers long from the Hunt's Point pedestrian bridge to the 148th Avenue overpass. Of seven ACO sites, two have been used exclusively for mainline observations (Yarrow Point and 148th Avenue); the rest have been used for ramp data collection (Hunt's Point, SR 908, 124th Avenue, and 148th Avenue--Bellevue and 148th Avenue--Redmond ramps). These sites are all located east of Lake Washington; to date, data have not been collected on the Seattle side of the lake. Like SR 516 on the I-5 South corridor, 148th Avenue NE has been treated as if it were three

separate sites. Data have been collected for morning westbound (on-ramps) and evening eastbound (off-ramps) traffic only.

Data collected for this corridor were not usable or available for the following locations: the Hunt's Point on-ramp AM westbound for Q4/92 and Q2/93; the 124th Avenue NE on-ramp AM westbound for Q1/93 and off-ramp PM eastbound for Q2/93; 148th Avenue NE mainline AM westbound for Q4/92 and eastbound for Q1/93; and the 148th Avenue -Redmond ramp, Q1/93. Sites #42 (Yarrow Point) and #45 (148th Avenue NE) have been the only active locations along this corridor since Q2/95. In Q2/97, counterflow observations were started at the Yarrow Point site.

I-90 Corridor

This corridor spans Lake Washington from 23rd Avenue S in Seattle to Front St. in Issaquah (between I-5 and SR 18), for a total of 23 kilometers. This corridor consists of nine ACO sites. Island Crest Way and Newport Way have been used for both mainline and ramp observations, whereas 60th Avenue SE, E Mercer Way, Bellevue Way SE, and Front St. have been ramp sites only. The site along the I-90 reversible lanes was added in Q3/94 for mainline ACO data, but data collection were not conducted between Q4/95 and Q2/97. Sites at 142nd Avenue and SR 900 were only considered during the initial testing period and have not been used since that time.

Island Crest Way was reported to be a poor vantage point in the mornings because of water sprinklers, landscaping, and the elevation of the overpass (4). Morning counts at this location were temporarily postponed during Q4/92 and Q1/93 because of the freeway landscaping project that was under way (which turned the location into a "sea of mud" following rain storms (4)). Data collected at the Island Crest Way on-ramp were not usable for Q1/93.

Observations at the E Mercer Way on-ramp were not scheduled for Q2/93 and Q3/93; observations at the off-ramp were not begun until Q1/93 because of construction;

and data for Q3/93 were not useable or were absent. Again, observations were scheduled for morning westbound traffic and evening eastbound traffic only. Observations were suspended in Q4/94 to free up resources for renewed observation at the Front St. site. Data for Bellevue Way are not available for the afternoon off-ramp eastbound site for Q3/93. Newport Way and Front Street in Issaquah were added during the third quarter of 1993 (Q3/93), and those data are included in this report with the exception of the following: Newport Way ACO data for Q4/93 and Front St. ramp ACO data between Q4/93 and Q3/94. ACO data are available for mainline sites at Newport Way (#57) and Island Crest Way (#54) only since Q2/97. In Q2/97, counterflow observations were started at the Island Crest Way site.

I-405 Corridor

This corridor is unique in a number of ways. Before it was partitioned for data collection in the third quarter of 1993, it stretched from Tukwila Parkway (at Southcenter) to SR 908 (north of SR 520, by Kirkland) for a total of 27.9 kilometers, and it had more sites than any other corridor (except the I-5 Downtown corridor, which has nine sites). Morning and evening data on both northbound and southbound traffic were collected within along this corridor since it contains a number of "activity zones". Although a large amount of data were obtained, there were so many locations that observations were not performed as often as desired. As a result, bad data affected a larger proportion of the observation quarters. To improve collection efforts, and in anticipation of more sites along this corridor, I-405 was divided into three sections, as described below.

I-405 South Corridor

This section begins at Tukwila Parkway and ends at 112th Avenue SE (Lake Washington Boulevard), for a total of 13.7 kilometers. It is the most complex section

because it runs through the suburban centers of Tukwila (where it merges with I-5), Renton, and Bellevue. Traffic here flows in multiple directions, traveling to and from both I-5 and I-90 towards Seattle, Tukwila, Renton, and Bellevue in the morning and returning in the evening. Although there are only four sites in this corridor, observations have been conducted to measure both morning northbound and southbound, and evening southbound and northbound traffic (similar to the I-5 Downtown corridor). Two sites (Tukwila Parkway and 112th Avenue SE) have been used solely for mainline observations during the period covered in this report. Three sites (SR 167, S Park Dr. and 112th Avenue SE) have been used for ramp data collection (as of Q2/93, ramp data collection from 112th Avenue SE was suspended). All ramp observations were discontinued as of Q3/95.

Data collected at Tukwila Parkway are unavailable for the morning northbound commute of Q3/92, and for the evening northbound commute between Q3/92 and Q1/93 because of bad data and the low number of counts performed. Counter-flow traffic data (morning southbound and evening northbound) were not collected during the winter months because of generally poor visibility and because they were not a high priority.

Ramp data for SR 167 were unusable for the evening northbound commute of Q4/92. For all other quarters in which data are missing, the reason is that counts were not scheduled. This ramp is not a healthy counting location because vehicle exhaust tends to accumulate here.

S Park Drive provides access to the Renton Boeing Plant, and so traffic patterns tend to be different here; peak periods run from 6:00-7:30 AM and from 2:00-4:00 PM; traffic is gone by 5:00 PM (4). Data for the northbound on-ramp traffic were not usable for the morning commute during Q4/92 and Q1/93 or for the evening commute during Q3/92 and Q4/92. Nor were they usable for the evening southbound commute during Q3/92 and Q4/92. During the period covered by this study, ramp improvement construction occurred at S Park Drive, which may have restricted the number of counts.

Data collection at all S Park Drive ramp sites was suspended in Q3/95. The reason that data are missing from any other quarters is that no sessions were scheduled.

At 112th Avenue SE, Q4/92 data were not usable for the GP lanes during the morning northbound commute and data were not usable for either the GP or HOV lanes of the morning southbound commute during Q3/92 to Q4/92. Both the evening northbound and morning southbound locations were counter-flow commutes, and thus observations were not begun until 1993. At all other locations for which data are absent, observations were not scheduled.

I-405 Central Corridor

This 2.2-kilometer section of I-405 centers around downtown Bellevue from SE 8th Street to NE 12th Street, between I-90 and SR 520. With the completion of a new outside HOV lane, observations at this site were relocated to NE 4th, which provides a better viewpoint. Of the two active ACO sites, NE 4th Street has been used for mainline observations, and ramp observations have been conducted at SE 8th Street.

Data for SE 8th Street were not usable for the northbound commute of Q3/92 or for the morning on-ramp commute during Q4/92 to Q2/93. Traffic for the morning southbound commute was so light (as demonstrated by Q3/92 data) that on-ramp observations here were discontinued until Q3/93. At all other locations for which data are absent, observations were not scheduled.

Observations at NE 8th Street were abandoned after a few trial counts during the third quarter of 1992, although additional counts were performed during the first quarter of 1993. NE 8th Street was a poor site for observations because the northbound on-ramp was too far away, and the traffic there moved too fast for observers to determine occupancy reliably. Although the southbound off-ramp was well-lighted, two lanes of traffic exited at the same time and moved too fast to count (4).

During the winter months, it was generally too dark to see the number of occupants when mainline observations were conducted at NE 12th Street because the lighting was inadequate (4). Morning northbound and southbound commutes were not scheduled until Q2/93; data collected for the evening northbound commute during the two counts of Q1/93 were not usable. Data collection since Q2/97 was conducted at site #73b (NE 4th Street).

I-405 North Corridor

Historically, only one site was observed along this corridor at the SR 908 interchange, 6.4 kilometers north of NE 12th Street. Mainline counts did not begin until Q3/93 and both ramp and mainline counts have been primarily conducted from the pedestrian bridge located here. Winter observations are difficult at the overpass because of poor lighting on the pedestrian bridge; better-lighted ramp locations at this site (such as the southbound on-ramp, which does not have a Jersey barrier) are not safe for observations (4). No observations were scheduled for the AM southbound on-ramp commute during Q2/93 and Q4/93 or for the PM northbound off-ramp commute during Q2/94. Between Q2/95 and Q4/95, a new outside HOV lane was added to the northbound and southbound freeway lanes. A new site at NE 160th St. (Juanita-Woodinville Way) was added during Q2/98 in response to WSDOT's request for additional HOV performance data along the northern sections of this corridor.

Outlying Locations

Starting in the third quarter of 1993, several new observation sites outside the original corridors were added to the scheduling log. These sites were chosen to provide baseline data for the areas surrounding Tacoma, Everett, Kent/Auburn, and Issaquah.

These sites are

- North I-5 at 112th SE in Everett (SB and NB, AM and PM) (Observations at this site were suspended between Q4/95 and Q1/98 because of budget constraints.)
- South I-5 at 70th E in Fife (SB and NB, AM and PM)
- South I-5 at the Tacoma Mall (SB and NB, AM and PM) (Data for Q3/93 are absent because of problems with the quality.)
- SR 16 at the Narrows Bridge in Tacoma (WB and EB, AM and PM)
- SR 410 at East Valley Avenue in Sumner (WB and EB, AM and PM)
- SR 512 at Ainsworth Ave./ Steele in Parkland (WB and EB, AM and PM)
- SR 167 at 37th NW in Auburn (SB and NB, AM and PM) (Observations were not scheduled until Q4/93 for AM SB and NB, and PM NB.)
- SR 167 at S 208th in Kent (SB and NB, AM and PM) (Data sessions were not scheduled for the following: PM NB in Q3/93, AM SB in Q4/93, and PM SB between Q3/93 and Q4/93.)

Only mainline ACO data have been collected at these sites.

CONCLUSIONS AND RECOMMENDATIONS

Occupancy data have been successfully collected from most of the study sites. Where data are unavailable, it is because an insufficient number of counts were scheduled or successfully completed. This happened for a number of reasons, including inclement weather, poor visibility, more sites than observers, and the discontinuation of data collection at some sites. The impact of having too few successful counts per quarter was that when bad data rendered the counts unusable, data for the entire quarter were possibly lost. During the first two years of the project, observation sessions were consistently more numerous for ramp than for mainline locations. This was because of the greater number of ramp locations and the better visibility they offered. There were also

proportionally more successful observations for GP lanes as a whole than for HOV lanes as a whole. This situation was corrected during the fourth quarter of 1994 with the adoption of a new counting procedure that involved rotating the lane to be observed between HOV and GP lanes. This procedure will provide sample sizes that are more comparable and enhance the validity of any comparison between HOV and GP lanes. However, in the third quarter of 1995, the total number of observations was reduced to ten count sessions per week because of a reduction in the funds allocated to the project. Funding for the '97-'99 biennium is sufficient enough to restore observations to the project's mainline observation areas with the option of including new or previously deactivated sites. At present, only mainline counts are being scheduled.

Factors not directly explored in this chapter include observer performance, and observer and data management; these are treated in greater detail elsewhere (1). Because observers are unsupervised in the field, they are trusted to begin and end observations on time and to observe and record vehicle occupancies accurately. Data quality is verified by checking individual files for "gross errors", such as misnamed files and repeated entries, and verified statistically by comparing current site data with site data collected from previous observations (see *HOV Monitoring and Evaluation Tool* (1)). As this project progresses, data will become increasingly accurate because of this method and will result in the emergence of a stable average as the volume of data increases. With this in mind, the following changes are recommended:

1. Continue to prioritize observations at locations that ensure the best use of resources. Safe locations that provide the best visibility over varying conditions, as well as ease of access and scheduling, are obviously preferred. Therefore, a directory of sites that includes site diagrams and a matrix of characteristics that affect data collection should be maintained. The question of whether counter-flow traffic patterns should be continued

or eliminated at existing locations, or expanded at additional locations, should be explored, as well as whether to maintain ramp data collection.

2. Evaluate the appropriateness of collecting vehicle occupancy data on the I-5 express lanes. Because express lanes contain both HOV and GP lanes, "before" data for this corridor may be useful in areas where express lane expansion is planned and would allow planners to monitor the express lanes' performance.

The occupancy data presented in this report provide valuable information in two areas: (1) the operation and performance of HOV lanes in comparison to GP lanes and (2) commuter mode choice in the greater Seattle area. Additionally, as the HOV lane system expands, areas where "before" data are now being collected will serve as baseline reference points in assessing the impact of HOV facilities on commuter mode choice. However, a caveat is in order: because loop data are more representative of traffic volumes in these corridors, the data included in this report should be used only to indicate the percentages of mode and vehicle occupancy in the corridors studied. The following chapter, "Average Car Occupancy Data Analysis," provides a treatment of these raw data and potential sampling bias.

CHAPTER THREE: AVERAGE CAR OCCUPANCY DATA ANALYSIS

The average car occupancy (ACO) data presented in this report are raw numbers. They are based on actual observations conducted between July 1992 and June 1998; they are not corrected for sample bias. The process for sampling time of the year, day of the week, time of day, lanes (or ramps), and locations, was designed to provide overall ACO figures that can be compared from year to year. The sample size is large enough that statistical variation is small, which allows for fairly accurate determination of the ACO at one location for a particular peak period in a given quarter. However, because ACO varies by time of the year, day of the week, time of day, lane (or ramp), and location, comparisons involving small subsamples (such as one location for a particular time period in a given quarter) must take these variations into account.

An example will illustrate the variations that must be considered. For instance, if one were interested in determining changes in the evening peak ACO in the northbound general purpose lanes at 145th NE on I-5 from the last quarter of 1992 to the first quarter of 1993, one would have to take into account the number of observations in each of the following categories:

- day of the week
- time period during the evening peak
- the particular general purpose lane in which vehicles were observed.

If ACO turned out to be always higher on Fridays (because of families or other groups traveling out of town together for the weekend, for example), a larger sample of Friday observations in the second quarter could point to the misleading conclusion that ACO was increasing. Despite controls in the sampling methodology, it is not always possible to sample in a way that will prevent all potential misinterpretations of the raw data.

This section of the report deals with this issue. The data from Phase I and Phase II of the study were analyzed to determine differences by time of year, day of week, time

of day, lane (or ramp), and location. Awareness of these differences may be helpful in adjusting for sampling bias (see Appendix D for an explanation and examples).

ANALYSIS METHODOLOGY

Statistical Package for the Social Sciences (SPSS) was used to convert ACO observation data for the entire year to a new format for analysis. ACO was calculated for each 15-minute period at each location for each lane (or ramp) during each quarter. Each ACO was then stored in a data file with its associated location, quarter, lane (or ramp), and time period identifiers. The SPSS data file contained 34,796 entries: 21,816 for observations in lanes and 12,980 for observations on ramps. Next, two separate files were created: one for freeway lanes and one for ramps. ACO figures based on fewer than 50 observations were deleted, and locations with fewer than 50 observations were also deleted. This reduction in the number of cases eliminated anomalous figures and reduced variability, but it maintained enough observations to conduct the analysis.

Following this reduction, 17,502 observations remained in the lane data file, and 10,755 observations remained in the ramp data file. Multiple regression was the general method for determining the influence of various factors on ACO. ACO was treated as the dependent variable, and various combinations of other information were used to determine the influence of factors such as location, time of day, day of the week, lane (or ramp), and time of year. The regression coefficients indicated the strength and direction of the influence of the factors of interest.

For instance, if the lane in which an observation was made was indicated by a dummy variable taking the value of 0 or 1 (depending on whether the observation was or was not in the lane), the regression coefficient for that dummy variable could be used to assess that lane's influence on its ACO. For example, if the coefficient for a dummy variable indicating lane 2 was .07, and the coefficient for lane 3 was .12, we could

conclude that the ACO was .05 higher in lane 3 than in lane 2 for the sample included in the regression. Furthermore, we could assess whether this difference was universal or was true only at some locations by comparing the regression coefficients for the total sample with the regression coefficients at each location. The differences in patterns of coefficients would indicate how locations varied. The regression coefficients for the overall analysis are shown in Table D1.

Differences in time of the year, day of the week, time of day, and lane (or ramp), were analyzed. Results are described in the following section.

TIME OF THE YEAR

Multiple regression was performed on all data using location, lane (or ramp), day of the week, and time of day, as well as dummy variables indicating the quarter in which an observation was made. By separating out the influences of all relevant variables, the independent influence of time of year could be assessed.

By using the summer quarter data as a baseline, the relative influence of the other quarters can be seen (see Table D1). These data revealed that the summer ACOs (third quarter) were higher than those from the rest of the year. The coefficients for the remaining quarters did not differ significantly with one exception. The ramp coefficient for the second quarter was significantly higher than that of the Q4 and Q1. The general pattern is that ACO is lowest in the fall and winter, rises somewhat in spring, and reaches its highest level during the summer. One explanation is the increasing number of non-commute trips that people take during the spring and summer.

LANE ANALYSIS

Lanes were classified by type: (1) HOV, (2) outer, (3) center, and (4) inner. The ACO in HOV lanes is obviously different from that in general purpose lanes;

consequently, the analysis concentrated on detecting differences among the general purpose lanes. The coefficient for the HOV lane is about 1.00 standard units higher than that in other lanes. This means that on average there was one more person in vehicles in the HOV lanes than in vehicles in the general purpose lanes.

The coefficients for inner and outer lanes did not differ significantly. However, the coefficient for the center lane was significantly lower than that for each of the two other lane types

TIME OF DAY

ACO is clearly higher during the evening peak than during the morning peak. ACO data were analyzed separately for each peak period; this analysis concentrates on the variations within each peak period.

An overall multiple regression was performed using dummy variables for each 15-minute period in separate analyses for each peak period. (Figures D1 through D4 show the adjustment factors (based on the regression) for each 15-minute interval for each peak period.) Ramps and lanes were analyzed separately. In addition, a regression was performed on the adjustment factors to determine the general patterns.

Data for the morning peak (for both ramps and lanes) indicated a tendency for ACO to rise during the entire peak period, with a slight tendency for ACO to be higher in the very early part of the morning peak. The rise was statistically significant for both ramps and lanes. The most likely explanations for this rise are as follow:

- Commuters who want to drive by themselves tend to leave earliest to avoid traffic.
- Commuting carpoolers can leave later and still take advantage of HOV facilities.

- Toward the end of the morning peak period, non-work trips begin to influence ACO.

There is a general tendency for ACO to fall during the evening peak. However, the evening peak pattern is clearly U-shaped, and this "U" is statistically significant. During the entire evening peak, non-commuters (who tend to travel in higher occupancy vehicles) are prevalent (in comparison to the morning peak). However, during the peak of the peak, commuters (primarily in SOVs) reduce non-commuters' influence on ACO.

DAY OF THE WEEK

ACO is lowest on Monday and increases throughout the week. The coefficient for Friday is significantly higher than that of all other days of the week. The rising trend during the week was found to be statistically significant. (Table D1 shows overall differences in ACO by day of the week.)

YEARLY CHANGES

When all factors were accounted for, yearly changes could be detected. Between the 92-93 period and the 93-94 period, there was a significant, but small, increase (.014) in the ACO with respect to lane data. However, there was a significant decrease in ACO (.011) from the 93-94 year to the 94-95 year. Ramp data revealed a similar pattern (A .006 increase, followed by a .02 decrease).

CONCLUSIONS

Many factors affect ACO. Therefore, it is important to design a sampling frame that reduces the influence of these factors. However, because it is impossible to perfectly sample all time periods, days of the week, lanes, and ramps at each location for the whole

year, it is important to consider these factors when changes in ACO are analyzed. After six years of data collection, we are confident in our understanding of these differences, but additional data will be important in confirming the analyses presented herein. Caution should be exercised in applying these correction factors. However, in conducting such detailed analysis, it is better to apply them than to use the raw data without adjustments.

CHAPTER FOUR: TRAVEL TIME DATA

Travel time data measure the time savings that HOV lanes provide over GP lanes. One commonly accepted standard for HOV lanes is that they must offer a time savings of at least 1 minute per mile. Another policy in Washington State guides decisions about occupancy requirements. According to the *Washington State Freeway HOV System Policy*, "HOV lane vehicles should maintain or exceed an average speed of 45 mph or greater at least 90% of the times they use that lane during the peak hour (measured for a six-month period)" (3). Travel time data collected in this project provide a variety of statistical information that will allow others to analyze time saving criteria when comparing HOV and GP lanes, and to apply lane performance criteria when evaluating HOV lanes.

Travel time data were collected using one of two methods outlined in the below. In the initial phases of this project the Baseline Travel Time method was used, but it proved too demanding on project resources to maintain. This gave birth to the Floating Car method [HOVTT (fcm)] which provided similar, but less reliable, travel time data. Both collection methods (and their findings) are discussed below, with brief explanations provided on their structure and methodology. Community Transit Automatic Vehicle Identification (AVI) travel times were also examined as a possible data source to supplement the HOVTT data, but hardware and technical support issues limited the reliability of this data source.

BASELINE TRAVEL TIMES

Study sections for this collection method were specifically chosen to bound the HOV lanes' beginning and end points along given corridors. For the average traffic speed of GP lanes, vehicles traveling in the fast (leftmost general purpose) lane were observed, and their license plates numbers were tracked. To determine HOV lanes' average traffic

speed, the identification numbers of Metro buses traveling in the HOV lane were recorded. Average vehicle speeds were calculated from the time differences between matches of these identification numbers recorded at the beginning and end points of given study sections. (See *HOV Monitoring and Evaluation Tool* for a complete explanation.)

While observations on all of the corridors were scheduled to capture regular commute traffic flows, observations on the downtown I-5 and I-405 corridors captured reverse commute traffic flows as well.

Travel time data were organized along the following parameters:

- corridor of study
- beginning and end site (study section)
- morning or evening peak period
- traffic flow direction.

The data (see Appendix E) were arranged to indicate, in 15-minute intervals, the average vehicle speed observed in HOV and GP lanes during the morning and evening peak periods by quarter (in miles per hour). Because GP lane traffic speeds were drawn from fast lane observations, they sometimes exceeded the speed limit (because of the lane's use as a passing lane). Because their number varied over the length of each study section, the number of GP lanes was not included.

From July 1992 to July 1993, travel time data were collected from 21 sites (mainly overpasses), organized into 26 study sections. Of these, only two locations, S 260th on I-5 South and 35th Avenue S on I-90, were at street level. Data were available from Q3/92 through Q2/93. In Appendix E, corridor diagrams that indicate the study sections precede the data; these are followed by diagrams for each site. Comments made by observers as they collected travel time data refer to aspects of data collection, traffic, and weather conditions; they are contained in Appendix H.

Data Availability

As indicated in the *HOV Monitoring and Evaluation Tool* final report, travel time data are difficult to obtain and expensive to produce for a number of reasons. Reliable data collection is hampered by a slow learning curve and the high amount of coordination required to schedule observations and ensure that collection periods match. In addition, factors associated with traffic patterns (such as vehicles changing lanes) can greatly reduce reliable data collection. Although a large number of travel time sessions were conducted in all of the corridors, it was difficult to obtain license plate matches during all peak-period times for all quarters. Consequently, quarterly average vehicle speeds are not consistently available for all given peak-period intervals.

In addition to the same weather-related problems that affect ACO data collection, travel time data are highly dependent on the number of successful license plate matches, which in turn is affected by several critical factors. First, gathering travel time data requires greater accuracy and faster reaction time than is required for gathering occupancy data. Therefore, this process is even more sensitive to conditions that reduce visibility. Second, gathering travel time data requires a "startup" period of at least 15 to 30 minutes, during which the vehicles observed at the beginning data point of a study section must travel to the specified end point before they can be observed and recorded. Third, the same license plates of passing vehicles must be recorded at each end of the study section, and for the same lane of traffic. Because vehicles rarely stay in the same lane, the likelihood that a vehicle has changed lanes or exited the freeway increases with the length of the study section. Fourth, observers cannot end and begin a session every half hour as they can when collecting ACO data; the breaks observers take add to the likelihood that a vehicle recorded by one observer will not be recorded by the other. Finally, average vehicle speeds can vary greatly from quarter to quarter.

Visibility

Rather than viewing and recording the number of persons in a vehicle with a single digit, as is done in the case of occupancy data collection, observers must be able to discern and record strings of license plate characters. Each character is smaller than the size of a business card (7 cm high by 2.5 cm wide), and vehicles can be traveling anywhere from 24 to 105 kilometers per hour. Complicating this is the fact that the license plate numbers are usually read from overpasses, which place the observer from 6 to 11 meters above the traffic flow. Poor visibility because of weather and lighting only compounds the problem by restricting the length of the sessions. Additionally, some observers find that they perform the task best when traffic is approaching them, whereas others collect data best from vehicles moving away from them. Where these observers are limited by sites to record license plates from traffic that is moving the wrong direction, less than optimal observer performance occurs.

Observation Session Length

Data are typically unavailable for the beginning period of the count because of the fact that the vehicles observed at the point of origin are not recorded at the end point until at least 15 minutes later, assuming that the observers even begin at the same time. This assumption is often not the case. Because two or more observers normally rely on a single vehicle for transportation to and from the sites, one observer has to drop off the other(s) before continuing on to the end site. Depending on the length of the corridor, this can add approximately 15 to 45 minutes to the start time of the session before matches can be expected (this is also true for session end times). If, as in the cases of I-5 and I-405, multiple travel time sessions are performed over long distances, the start-up time is greater.

Study Section Length

Successful matches depend upon the plates of the same vehicles being recorded in the same lanes at both ends of a study section. The distance from the beginning to the end site of a study section, therefore, directly influences the number of successful matches because vehicles rarely remain in the same lane. As the distance between observation sites increases, the likelihood that the same vehicle will be recorded decreases because the driver is more likely to have changed lanes or to have exited the corridor altogether, depending on the availability of access/egress ramps. Furthermore, because GP vehicle speeds are derived from fast lane observations, the number of successful matches may be reduced because of the fast lane's use as a passing lane. (For a list of the study sections and their respective lengths, see Table E2).

BASELINE TRAVEL TIME SITES

I-5 North Corridor

The I-5 North corridor is 8.2 kilometers long. It has three observation sites and consists of two study sections from which data were collected:

- 236th Street SW to NE 117th Street for morning inbound traffic
- NE 117th Street to NE 185th Street for evening outbound traffic

236th Street SW was selected because it was the northernmost site at which HOV lanes operated up to Q3/96; for this reason it was kept despite the fact that N 185th was later determined to be a better location (4). Both 236th Street SW and 117th Ave. NE had sidewalks on the north side only; consequently, observers had to count vehicles

coming toward them in the morning and going away from them in the evening (Figures E2 and E4).

For 236th Street SW to 117th St. NE (Table E3), fewer data were available for the morning commute because the study section was longer (see Table E2). Observations for both the winter (Q4/92) and spring quarters (Q1/93) were affected by inclement weather and a shorter daylight cycle, as indicated by the lack of data for the early morning (Table E3) and late evening (Table E4). For Q1/93, data were unavailable because only one count was performed for each section, and no reliable matches were made.

I-5 Downtown Corridor

This is the second longest corridor at 18.8 kilometers long. It has four sites organized into six study sections:

- between Lakeview Boulevard E and S Holgate Street
- between Lakeview Boulevard E and Albro Place
- between Lakeview Boulevard E and S 144th Street
- between S Holgate Street and Albro Place
- between S Holgate Street and S 144th Street
- between Albro Place and S 144th Street

Lakeview Boulevard E was chosen to be the northernmost site of this corridor because it was also being used for vehicle occupancy collection (the HOV lane actually began further south, at Mercer). Although Lakeview Boulevard E was discontinued for occupancy counts, it continued to be used for travel times through Q2/93 (Tables E5 through E9). S Holgate Street was a difficult site to collect data from because it was uncomfortable for observers to sit at and had poor visibility (Figure E7). Its one sidewalk was on the north side. The overpass, situated on a steep hill, placed the observer in an awkward sitting position. Southbound traffic was 6 meters lower than northbound traffic,

and in the morning sun, license plates were difficult to see because of the shadow cast by the overpass (4). Visibility was good at Albro Place in both directions, but observers complained of the diesel fumes that collected there (Figure E8) (4). S 144th Street was the best location because it had wide sidewalks on both sides of the overpass (Figure E9).

Except for a few study sections where the distances between sites were short, travel time data for this corridor were sparse. Again, data were less available for the winter quarters, as well as for the longer study sections (such as Lakeview Boulevard E and Albro Place). Although HOV lane observations were successfully performed for each of the above study sections, no reliable matches were obtained from any of the data collected.

For the morning southbound commute from Lakeview Boulevard E to S Holgate Street, no data were successfully collected during Q1/93 (Table E5); for the evening southbound commute, no data were successfully collected during Q4/92 (Table E6). On Lakeview Boulevard E and Albro Place, one count each was successfully performed and matched during Q3/92 and Q4/92 of the morning southbound commute (Table E7); for the evening southbound commute, two successful counts were reliably matched for Q3/92, and one count for Q4/92 (Table E8) At the same study section for the morning northbound commute, data were successfully collected and reliable matches were obtained for only Q3/92 (Table E15 and E16). Of the one successful count performed at Lakeview Boulevard E and S 144th Street for the evening, southbound commute, one match was made (Table E9); no reliable matches were found from the single count performed for the morning northbound commute (Tables E20, E10, E11). For the morning northbound commute at S 144th Street to Lakeview Boulevard E, no reliable matches were obtained from the one successful count performed during Q3/92 (Table E20).

For the S Holgate Street to Albro Place study section, data were collected successfully for the morning southbound commute during Q3/92 and Q4/92 only (Table

E12). For S Holgate Street and S 144th Street, data were only collected and matched for evening, southbound traffic during Q3/92 and Q4/92 (Table E14); no data were successfully collected for the morning, northbound commutes (Table E21). For the Albro to Holgate study section, no data were successfully collected for the morning northbound commute during Q2/93 (Table E17); data were successfully collected for the evening northbound commute only during Q2/93 (Table E18).

I-5 South Corridor

The I-5 South corridor was one of the project's more successful travel time data collection sites. This corridor is 8.9 kilometers long, had three sites, and consisted of two study sections from which data were collected:

- S 178th Street to S 216th Street for evening outbound traffic
- S 260th Street to S 216th Street for morning inbound traffic

Although a great deal of data were collected for the morning commute at S 260th Street to S 216th Street (Table E24), S 260th Street was a difficult and unsafe location at which to collect data. The site was located on the median dividing the northbound and southbound lanes, rather than on an overpass (Figure E13). To reach this site, observers parked on the underpass and scrambled up a steep dirt hill and around a chain link fence while carrying a folding chair and a laptop computer (4). In rain, the hill became very muddy and slippery (4).

Summer data for S 178th Street to S 216th Street were available later in the day than for any of the other travel time study sections. Data were collected until 7:15 PM to take advantage of the longer period of available daylight during that period (Table E23). Visibility for this corridor was adequate at all of the sites.

SR 520 Corridor

The SR 520 corridor is 7.9 kilometers long, from Hunt's Point to 148th Avenue NE, and includes SR 908. This corridor was divided into three study sections, and data were collected for morning inbound and evening outbound traffic:

- Hunt's Point and SR 908
- Hunt's Point and 148th Avenue NE
- 148th Avenue NE and SR 908.

The location at Hunt's Point was a pedestrian overpass four blocks west of the vehicle overpass (Figure E15). It was particularly good for collecting data because observers could see well in both directions, and traffic was always almost stopped, which made it easy to record license plates (4). The only distinguishing feature of 148th Avenue NE (Figure E17) was that it carried a great deal of traffic, and observers reported that the occupants of passing vehicles often stared at them (4).

Although the study sections on this corridor were generally better than those in other areas, HOV lane data were very limited because the only HOV lane was an outer lane running from SR 908 to Hunt's Point for westbound traffic (sites 41 and 43 on Figure E14). Data on "reverse flow" traffic were briefly collected; evening sessions were conducted on the westbound traffic from Hunt's Point to SR 908 for Q3/92 and then were discontinued because of the insufficient number of matches for the HOV lane (Table E26). Data were not collected from the 148th Avenue NE to Hunt's Point section for morning westbound traffic until Q4/92 (Table E27). Data for evening eastbound traffic are missing for the winter quarters (Q4/92 and Q1/93), despite a relatively high number of sessions that were scheduled.

I-90 Corridor

The I-90 corridor is 7.7 kilometers long and consists of two study sections from which data were collected:

- E Mercer Way to 35th Avenue S for morning westbound traffic
- 23rd Avenue S to E Mercer Way for evening eastbound traffic.

The neighborhood around 23rd Avenue S was not considered safe, especially in the dark for women, so male observers were preferred; this affected scheduling (4). Furthermore, observers had to stand to see the traffic because of the 1.2-meter high wall (Figure E19). Observers relied on either of two locations for observations at 35th Avenue S: they sat on the retaining wall on the overpass or on the bicycle path that is on the same level as the lanes, looking across traffic (Figure E20). Getting to this site was time-consuming because of the winding roads on Mercer Island; consequently, counts tended to begin later than usual--especially if a "drop-off" was involved (4). The retaining wall position, although less comfortable, offered better visibility. Visibility from E Mercer Way was adequate, although the location was heavily landscaped (observers were often sitting in bark mulch) (Figure E21).

Travel time data collection was successful for this corridor as well, except for two winter quarters for which data are unavailable. For 23rd Avenue S to E Mercer Way, data are unavailable because no matches were obtained from the four sessions for Q1/93 (Table E32); the same problem occurred for E Mercer Way to 35th Avenue S during Q4/92 (Table E33).

I-405 Corridor

This corridor is the longest of the six corridors--27.5 kilometers, with ten study sections (also the most of any corridor). Because of the complexity of traffic patterns

(see Chapter 3, pp. 27-30), observations were conducted to capture both regular and reverse traffic flows at the following locations:

- Tukwila Parkway and Benson Road S
- Tukwila Parkway and 112th Ave. SE
- Tukwila Parkway and NE 12th Street
- Tukwila Parkway and SR 908
- Benson Road S and 112th Ave. SE
- Benson Road S and NE 12th Street
- Benson Road S and SR 908
- 112th Ave. SE and NE 12th Street
- 112th Ave. SE and SR 908
- NE 12th Street and SR 908.

This was the least successful corridor for collecting travel time data for a number of reasons. The root problem was that, unlike the corridor for the occupancy data, I-405 was not segmented into south, central, and north corridors because the study sections spanned the corridor's entire length. First, observation sessions were spread too thin. An average of only one to two counts were successfully performed for each applicable parameter (site, commute period, traffic direction). Second, most study sections were too long to obtain matches reliably. All but one were longer than 5 kilometers (Table E2) and had numerous access/egress ramps in between (Figure E23), thereby increasing the likelihood that observed vehicles would have changed lanes or exited the corridor altogether.

HOV data for the longer study sections are unavailable for similar reasons, and because the HOV lanes were neither continuous nor remained on the same side of the corridor. Inside HOV lanes began at Tukwila Parkway and ended at Benson Road S; yet from NE Park Drive to 112th Avenue SE, HOV lanes were on the outside. There were no

HOV lanes in the central and northern portions of the corridor during the time of this study. During Q2/93, data were only collected between the shorter study sections: Tukwila Parkway to Benson Road S (Tables E34, E35, E41 and E42); Benson Road S to 112th Ave. SE (Tables E43, E44, E50 and E51); 112th Ave. SE to NE 12th Street (Tables E52, E53, E60 and E61); and NE 12th Street to SR 908 (Tables E62, E63, E68 and E69).

Tukwila Parkway, 112th Avenue SE/Lake Washington, and NE 12th Street were average sites for collecting data (Figures E24, E26 and E27, respectively). Benson Road had good visibility and a wide sidewalk on the west--the sidewalk on the east side was very narrow (Figure E25). Observers recording travel time data from the pedestrian bridge at SR 908 during the winter had the same difficulties as they had experienced with occupancy data collection efforts (Figure E28).

COMMUNITY TRANSIT AVI PROJECT

In 1992, Community Transit (CT) and WSDOT began a project to equip all of CT's Seattle express buses with automatic vehicle identification (AVI) systems. The system consists of three parts: a transmitter located under the bus, the use of induction loops embedded within the freeway as antennas, and a roadside receiver to record incoming data. The system piggybacks a signal on a freeway induction loop containing the bus' identification code and records the time, date, and location of the transmittal. At three-month intervals the data are downloaded and transferred to a personal computer for further processing.

In an effort to supplement the HOVTT travel time data, these records were analyzed to produce travel times and travel speeds along the North I-5 corridor between NE 120th St. and NE 185th St. for both the southbound and northbound direction. The methodology used to process the data utilized basically the same principles as the HOVTT analysis ("time stamps" and distance calculations) but to a higher degree of

accuracy and precision because of the collection method. In an effort to make the AVI data more comparable to the HOVTT data, only data within the given peak commute periods (6:00-9:00 AM and 3:00-6:00 PM) were considered for determining travel speeds. AVI data were not available between Q2/96 and Q2/97 because of sound wall construction along the I-5 North corridor. Use of this data as a supplemental source of travel time data was discontinued Q1/98 due to various hardware and technical support issues.

HOVTT (FCM) PROJECT

The collection of travel time data using the license plate matching method required a substantial investment in personal, equipment, and time. Several alternatives were examined to determine the most favorable collection method, given the constraints imposed by the project's financial limitations. The HOVTT (fcm) program was the result.

Data collection is facilitated by sending observers out into the peak hour commute to record real-time spot checks of the HOV system. Observers are instructed to observe the flow of traffic within the HOV lanes and to maintain a speed equivalent to other HOV commuters. These sessions require two observers (three on SR 520) to satisfy the HOV lanes' vehicle passenger requirements: one person to drive and the other to run the data collection program. The HOVTT (fcm) program records travel times through a series of "time-stamps" entered when the observer reaches a designated point along the freeway. During a session observers loop along a given corridor collecting travel times for each period they traverse a section. Currently, eight corridors are under observation within the Puget Sound region and are defined further in Appendix F.

Determination of Travel Speed

On a weekly basis all of the HOVTT files created go through an analysis process to convert these record "time-stamps" into useable travel speeds. This is accomplished by linking each "time-stamp" with the milepost of its data entry point. The milepost of each point was determined from the State Highway Log, and final travel speeds deduced by examining consecutive data entries within any given file to find the distance between them and the time elapsed. The resulting travel speed is the quotient of the distance by the time differential.

Results are recorded in weekly reports that catalog the file's name, the observer's name, the section speeds recorded, and any data errors and/or adjustments made to the data. Occasionally errors are made when the data are entered, and adjustments are necessary. These errors are quite evident, and all time corrections are documented on both the weekly report and within the file itself.

Limitation of Analysis Procedure

Although this method is very efficient in a financial sense, the data's sensitivity to true travel times are dependent on a variety of factors. Things such as the observer's driving style, the exact point of data entry, weather conditions, congestion levels, adjustment of data errors, and day of week all have an uncertain effect on travel times. Normally, variances within the data are accounted for by obtaining a large sample size. Utilizing this method of data collection results in relatively small sample sizes. Therefore, anyone drawing any conclusions from the data presented herein should be warned that these results can not be considered statistically significant.

Interpretation of Data and Graphs

Appendix F represents the performance summaries of all corridors under observation between October 1, 1995, and March 31, 1998. There are several tables for

each corridor, one for each direction of travel (e.g., southbound, northbound, westbound, eastbound) and peak commute period (e.g., AM or PM). Tables are divided by corridor sections and include the following values: the minimum and maximum speeds, the median speed, the average speed, the standard deviation of the data population, the 90th percentile travel speed (speed that 90 percent of the data points exceed), the percentage of data points exceeding the 45 mph criterion, and the number of data points. The tables in Appendix G are divided by the same corridor sections and provide average speed data that compare the performance of HOV lanes to adjoining general purpose lanes. Corridor section numbers are organized by increasing milepost (generally south to north or west to east).

HOVTT (FCM) DATA RESULTS

HOVTT data continued to show that the HOV system within the Puget Sound provide a sizable benefit in travel time savings. Table 4.1 summarizes the travel time savings observed along the various corridors during Q1/98.

Each of the corridors is examined to determine the benefits experienced by HOV commuters and whether performance levels satisfy the criterion established by Washington State Freeway HOV System Policy. When possible trends are evaluated, only data from the same quarters (e.g. Q1/96 vs. Q1/97) will be examined to minimize seasonal fluctuations of travel times. Each of the corridors is also examined to determine where a section of the system has failed to meet the criterion and an attempt is made to provide a possible reason for the low speeds.

Table 4.1: Travel Time Savings in Seconds per Mile (spm) between HOV Lanes and General Purpose Lanes Determined from Weighted Average Speed

Observation Corridor	Southbound (& WB)		Northbound (& EB)	
	Morning	Evening	Morning	Evening
I-5 North	12.5	15.5	5.8	2.6
I-5 Downtown	2.9	9.7	3.6	35.9
I-5 South	0.1	12.3	8.9	2.9
SR 520	11.5	151.6	N/A	N/A
I-90	4.6	1.5	2.2	7.2
I-405 South	6.2	26.2	102.8	14.6
I-405 North	16.7	2.4	1.5	21.4
SR 167	4.1	5.5	18.5	14.9

I-5 North

In September 1996 a new segment of HOV lane opened in the northbound direction between NE 185th Street and 164th Street SW in Lynnwood. Over the last three quarters of observation, northbound performance levels continued to outshine those observed before the opening of the HOV lane extension. Most sections surpass the HOV policy criterion with an impressive stability in travel speeds realized by evening HOV commuters. Opening the section of HOV lane between NE 185th St. and Lynnwood was instrumental in stabilizing travel speeds along this section of freeway.

However, one particular concern was the decline of performance levels during the southbound morning peak period for any given quarter in relation to the commuters' proximity to the express lane entrance. This reduction in speed may be due to friction with congested adjacent general purpose (GP) lanes. WSDOT is constructing a new lane configuration at Northgate to help alleviate this tension and elevate travel speeds. The current southbound morning performance levels showed an increase in comparison with the previous year's levels, with average travel speeds favoring HOV commuters by 6 mph

(10 kph) to 15 mph (24 kph). HOV traffic moving in the opposite direction of the peak commute (e.g., northbound AM and southbound PM) had no problem meeting the selected standards. A new segment of HOV lane from 164th Street SW to the SR 526 (Mukilteo Speedway) opened July of 1998 extending this corridor by 5.7 miles.

I-5 Downtown

The HOV lane southbound through the downtown Seattle corridor was recently extended from its previous terminus at the Boeing Access Road to the I-405 interchange providing a continuous HOV lane from Federal Way into Downtown Seattle. Thanks to the added HOV capacity, performance levels during the southbound evening commute continue to exceed the state's HOV policy regarding travel speed and reliability. Commuters traveling along the HOV lanes continued to enjoy travel time savings of 35.6 seconds per mile (spm) during the northbound evening commute and 9.7 spm during the southbound evening commute. The largest concern along this corridor continued to be decreased performance levels near the northern terminus of the northbound carpool lane. One final trend was the apparent decline in performance levels for sections between Albro Place and Holgate Street. This trend is due to construction by WSDOT to seismically retrofitting the bridge columns along this section of freeway.

Collection along this corridor was performed on a low priority basis. This means that sessions were usually conducted on the way to and returning from other corridors, rather than targeting the corridor itself. Therefore, data for the downtown HOV lanes were usually collected at the beginning and/or end of the peak commute time. The result may be that observed trends were biased or skewed.

I-5 South

Performance along the HOV lanes between Southcenter and Federal Way was consistent with previous quarters' observation. The I-5 South corridor did not satisfy the

HOV policy requirements during the southbound evening peak commute. Performance levels dropped significantly during Q1/98 when compared with levels for the same period of the previous year, but southbound HOV commuters still realized travel time savings of 12 spm, even with the current heavy levels of congestion. One should note that construction along the Southcenter Hill was still ongoing during Q1/98 observations. The new HOV lanes passes through the I-405 interchange so that buses can maintain their speeds up the incline at the Southcenter Hill.

SR 520

This HOV lane is not utilized as heavily as other HOV lanes because of its 3+ person requirement. The HOV lane is squeezed in on the right shoulder, primarily to allow freeway flyer buses a congestion bypass route to the Evergreen Point floating bridge. The result is a lane that possesses little or no shoulder, blind corners, and problems with merging ramp traffic. All of these reduce travel speeds for the HOV commuters. Understandably, no sections along this corridor met the travel speed criterion. A brief study of the situation would reveal that the problem with the lane is not limited capacity but drawbacks in design and function. Because of equipment problems and time limitations, a complete set of data was not collected for this corridor.

I-90

HOV lanes along the I-90 corridor were relatively free of congestion in all directions and at all peak commute times. The data have remained uniform over the history of the project, with travel speeds concentrated near the posted limits. This corridor was also designated as a low priority, but these trends were supported by I-90's history of lower congestion levels. Apparently, the system here performed above expectations and needed no additional design measures. Observers did comment that

traffic along the general purpose lanes between East Mercer Way and downtown Seattle appeared to be more congested than in previous quarters.

I-405 South

WSDOT completed its restriping project in February 1997, effectively eliminating the HOV lane cross-over at the Renton S-curves, and successfully relocated the HOV lanes to the inside of the freeway as far north as the I-90 interchange. The result is an HOV lane that provides consistent, fast travel along its entire length. Performance levels during all peak periods and directions have improved dramatically over those recorded before the restriping project.

The freeway here continues to support peak commutes in both directions of travel beyond the capacity of the road's two general purpose lanes. Southbound performance levels continue to exceed those recorded during the first quarter of 1996 by approximately 10 percent to 20 percent, but performance levels lagged behind the HOV policy criterion in a few key areas, namely the SR 167 interchange and the I-5 interchange. The evening commutes benefited greatly from the switch with sizable improvements in performance levels along all affected sections.

The biggest highlight of this corridor was the travel time savings achieved by HOV commuters. During Q1/98, the HOV lanes along the I-405 South corridor obtained travel time savings ranging from 6.2 spm to an amazing 102.8 spm (1 min. and 42.8 sec per mile). In general, the switch of the HOV lanes to the inside lane increased the stability of travel time for HOV users.

At this time, travel time data collection is not scheduled to begin again until October 1998, with the next quarterly report due January 1999. Future plans call for relocating all remaining I-405 outside HOV lanes to the inside lane. This reconfiguration should help reduce instability in travel speeds along the Eastside HOV system.

I-405 North

HOV performance along this corridor varied greatly, depending on the time of commute. The morning peak period faired better than the corresponding evening commute. Only two sections failed to reach the 45 mph standard during the morning commute during Q1/97: southbound between NE 124th Street and SR 908 in Kirkland (58.1 percent), and northbound along the southern terminus (83.3 percent). Results from the evening commute made evident several areas of concern along both directions of travel.

Northbound HOV lane performance was variable, with several sections posting 5 percent to 20 percent decreases in performance levels making evident two areas that need improvement. The first was the weave problems produced by the SR 520 interchange. The second was the back-ups between NE 124th Street and the northern terminus of the HOV lanes. In November of 1996, the HOV lanes at the NE 160th Street Overpass were opened, but they did little to alleviate congestion levels at the terminus of the northbound HOV lanes because of new construction on the SR 522 interchange.

The most alarming issue along the southbound HOV lanes was the apparent decline in performance levels. Further analysis of the HOVTT data showed that the decline in performance levels originated from two possible areas of concern. The first was the Totem Lake on-ramps (NE 124th St.), where high levels of morning commute traffic merge through the outside HOV lanes. The second centered on sections south of the SR 520 interchange that pass through Bellevue's CBD. As stated before, the HOV lanes will eventually be switched to the inside, which may help stabilize travel speeds through these problem areas.

SR 167

These HOV lanes, opened in November of 1994, performed well in both the morning and evening peak commutes. HOV performance along the commute direction

(e.g., northbound AM and southbound PM) was encouraging, with average travel speeds in the mid-to-upper fifties and travel time savings ranging from 4.1 spm to 18.5 spm.

Currently, this corridor is undergoing heavy construction between the HOV lanes' southern terminus and SR 18 as work continues to add another 5.5 miles of HOV lane in each direction. This project is scheduled for completion in autumn 1998. With further expansion of this route, the need for a complete freeway-speed interchange between I-405 and SR 167 will continue to grow. The present collector-distributor design is grossly inadequate for the level of demand.

CONCLUSIONS AND RECOMMENDATIONS

Although the effort to collect reliable travel time data using the matching license plate method was educational, the usefulness of the baseline travel time data presented in this report is limited. Although the data can generally be used to compare HOV lane performance to GP lane performance and to identify areas of congestion, a number of factors render data interpretation difficult. Baseline travel time speeds can only be compared by time of commute for the quarter in which they occurred. Because the data are presented as average speeds, only individual study sections may be used; the data should not be aggregated to examine the differences between HOV and GP lanes corridor-wide.

It was much more difficult and complex to collect baseline travel time data than it was to collect vehicle occupancy or floating car travel time data. Observers not only had to be more accurate and have better visibility, they also had to coordinate their efforts more carefully. Even with good data, matches were difficult to obtain because of normal traffic behavior (e.g., lane changes), especially over long distances. Intervening access/egress ramps in study sections only compounded this problem. Despite the obstacles that made it difficult to collect the baseline travel time data, the experience

gained in this study indicates that travel time data may be collected successfully under some conditions. The greatest quantity of baseline travel time data was gathered at study sections characterized by good visibility, short length, and high numbers of successful observations. If manual baseline travel time observations are re-established, the following recommended actions should make the data collection effort more successful:

1. Use short travel time study sections. To decrease the likelihood of observed vehicles changing lanes or exiting the corridor, distances between sites should be short (for example, under 3 kilometers) and chosen to limit the number of intervening access/egress ramps.

2. Conduct more travel time data collection sessions per study section. Although a number of factors reduce the likelihood of obtaining reliable license plate matches, one way to compensate is to increase the number of data collection sessions, thereby increasing the volume of license plates collected.

3. As a special study, conduct travel time observations using the express lanes. Not only do the express lanes have GP and HOV designations, they also constitute a "captive audience" in that vehicles may not exit for longer distances. As a result, it may be easier to obtain the matches necessary for reliable travel time data.

Effective collection of baseline travel time data requires a great deal of coordination between observers to ensure that they begin and end at the same time, as well as corridor sections that facilitate license plate matches. Even when travel time data are effectively collected, they can vary so much that routinely gathering data to establish

an "overall" travel time statistic for a length of corridor may not be very useful. Because of this fact, future travel time data will be collected by means of the floating car method outlined above. The following recommendation is proposed to better facilitate the collection of HOVTT (fcm) travel times.

4. Index funding for data collection efforts with the opening of new HOV lane miles: Maintaining current HOVTT (fcm) and ACO data collection for all sites originally observed during the baseline data collection period is required to evaluate the effect HOV lanes have on regional traffic patterns. Additional support will be required from associated agencies as new HOV lane miles are added to the system to maintain the level of observations required to produce significant samples of data for HOV lane evaluations.

It is important to maintain levels of data collection so that time based trends are not missed because of insufficient data. To maximize the project's resources, travel time data will be collected during the first and fourth quarters of each year, when limited light conditions make ACO data collection less reliable. Summary data tables are located in Appendix F and G.

CHAPTER FIVE: PUBLIC OPINION SURVEY

The research methodology used to collect the data described in this chapter is detailed in the companion report, *HOV Monitoring and Evaluation Tool* (1). Users of these data should be aware that the sample used in this survey was not intended to represent the actual driving population. Rather, this portion of the project attempted to generate comparable samples of single occupant drivers and carpoolers to measure differences in their attitudes about HOV lane use and effectiveness. However, the sample generated for this survey comprised 64 percent SOVs and 36 percent HOVs. This may be because travelers identified as driving HOVs may have been carpooling under special circumstances when observers recorded their commute mode in the field. In addition, the survey was mailed to each vehicle's registered owner and thus may not have been received by the driver observed in the field. Only 44 percent of the drivers originally identified in the field as HOVs reported that they actually rideshare on a regular basis. On the other hand, 20 percent of drivers originally identified as SOVs reported that they rideshare on a regular basis. This underscores the uncertainty of correctly linking commute mode on any given day to overall mode choice. It is also important to note that this survey was intended to measure only attitudes about HOV lane effectiveness, not the underlying reasons behind individuals' choices to drive alone or to rideshare.

Three supplemental pieces of information were recorded with each returned survey. First, the postage date was entered to measure changes in opinions over time. Second, data entry staff recorded the commute mode in which survey respondents were traveling when they were observed by the traffic counters. Third, each survey was assigned a document number so that the phone numbers and addresses of respondents who indicated their willingness to answer follow-up questions could be retrieved from storage.

Between July 1993 and June 1998 surveys were mailed to 38,219 owners of vehicles identified by traffic observers in the field. Drivers of vehicles identified as HOVs received 17,590 surveys; 4,118 returned them, for a response rate of 23.4 percent. Drivers of vehicles identified as SOVs received 20,629 of the surveys; 4,473 returned them, for a response rate of 21.7 percent. The response rate for the entire survey population was 22.5 percent. These values represent a .9 percent decrease in the response rate from the survey period that ended May 1996. The current size of the survey database compiled since November 1992 is 8,591 cases.

In addition to providing results from all questions on the questionnaire, this section contains several examples of how to use the survey data in conjunction with other data gathered for this project. The purpose of this project is to develop a wide ranging source of data that will allow analysts to evaluate the performance of the HOV lane system. Therefore, illustrative examples that demonstrate how to combine the disparate sources of data are provided, rather than a comprehensive analysis. Subsequent quarterly reports will contain additional examples of noteworthy trends and changes from the baseline data.

The bulk of the survey data is presented in aggregate form, treating SOV drivers the same as carpoolers. However, opinion data are presented by splitting these two groups. Many of the figures are based on data collected from January 1997 until June 1998 to better illustrate the changes in demographics and opinion since the previous survey period. Any changes in opinions or trends were examined, and the results are presented in a graphical format. A copy of the public opinion survey is contained in Appendix I, and comments by survey respondents are presented in Appendix J.

TRAVELER DEMOGRAPHICS

To better acquaint users of these data with the survey population, demographic data are presented before sections relating to driving patterns and opinions on HOV lane effectiveness. This presentation of the results does not correspond with the order of the questions as they appeared on the survey, but it will facilitate interpretation of following sections.

It was impossible to ensure that the actual driver of the auto observed in the field would respond to the survey if more than one person in the house commuted to work. Therefore, we asked that the survey be filled out by the person in the house who commuted most often.

Figure 5.1 depicts the gender of survey respondents. In Figure 5.2, the distribution of the respondents' age is shown. Figure 5.3 examines the level of education respondents have reported.

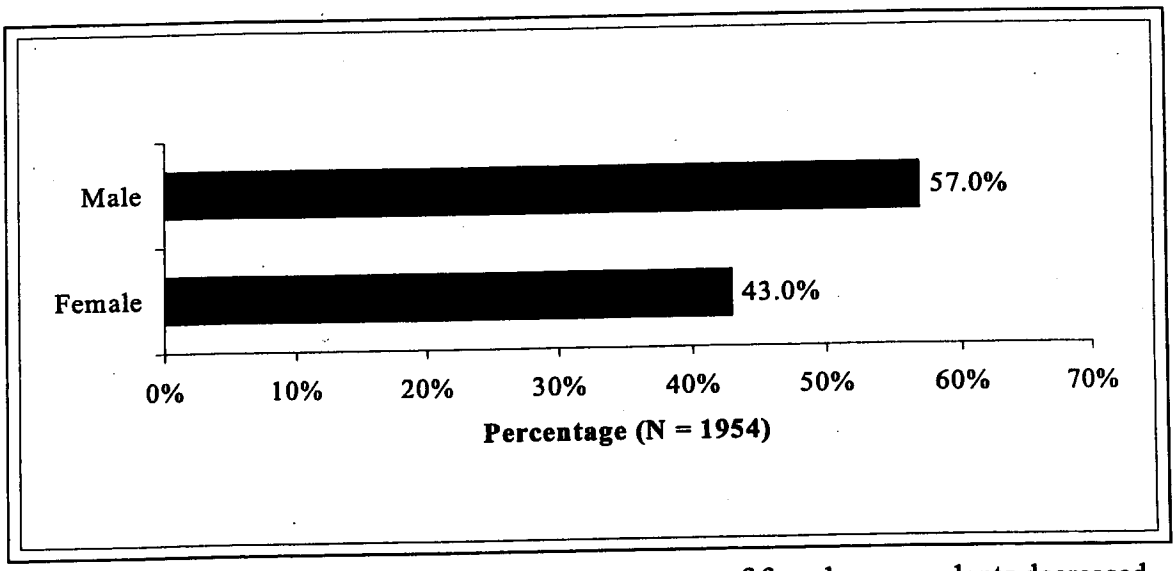

Figure 5.1 Gender of Respondents: The percentage of female respondents decreased slightly in comparison to previous results.

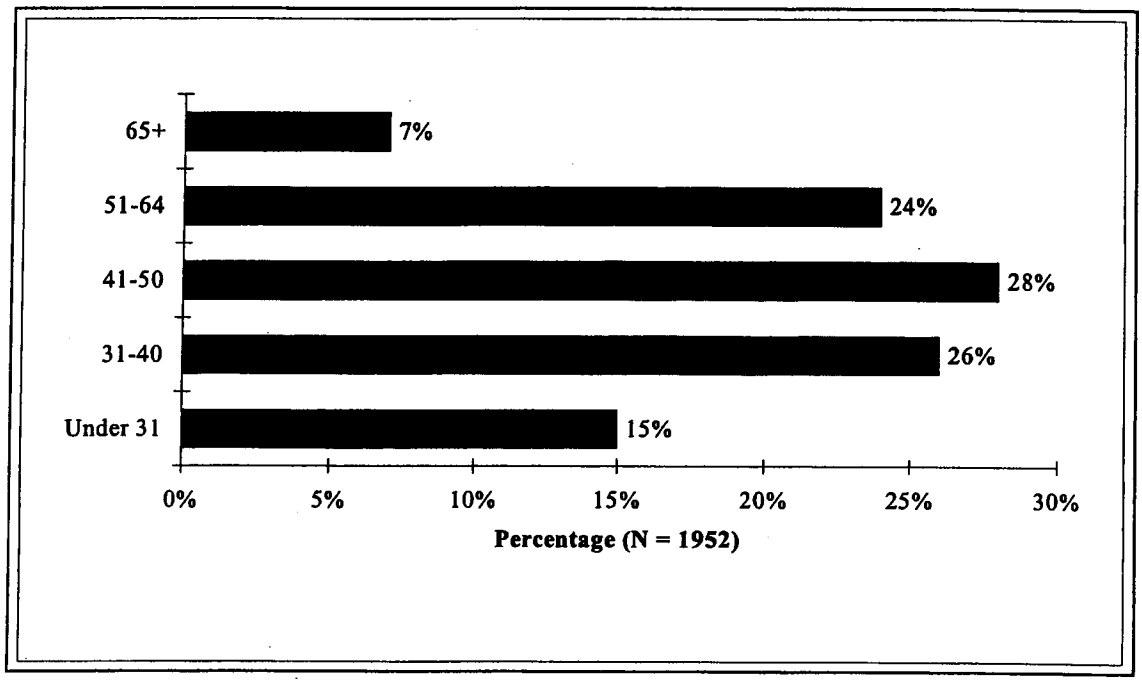

Figure 5.2 Age of Respondents: The overall age distribution of peak hour commuters is shifting when compared with the results of the 1996 report reflecting an aging population.

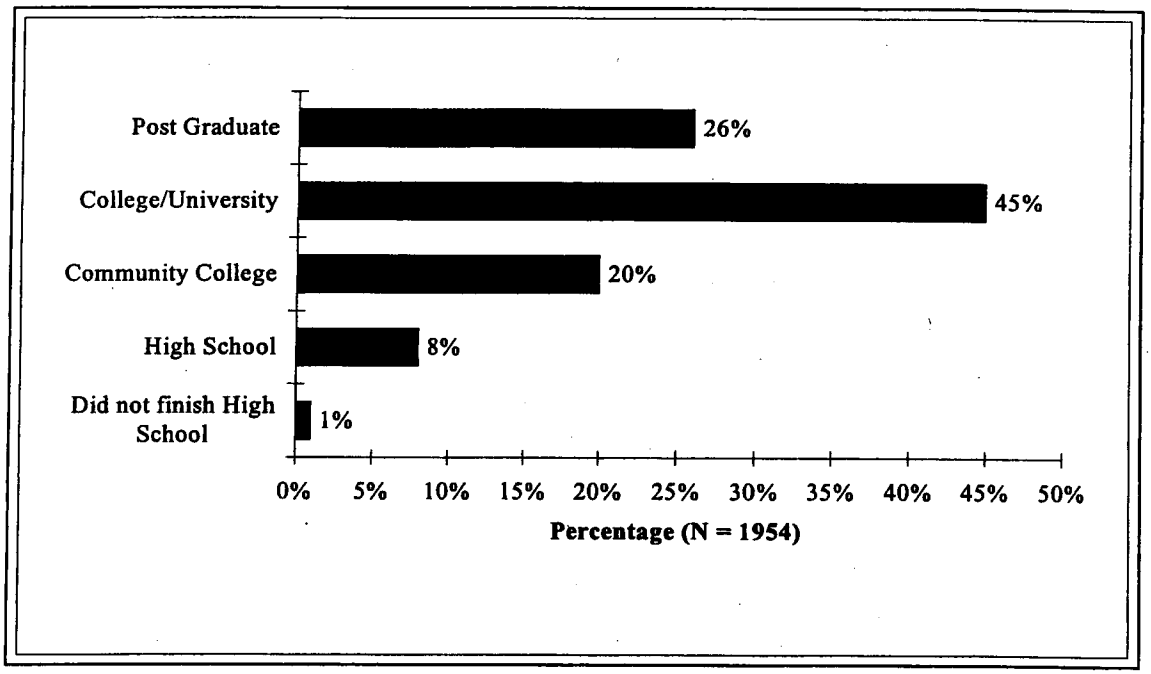

Figure 5.3 Education Level of Respondents: Seventy one percent of survey respondents possess a college degree or post-graduate education. People with a relatively high level of education may be more inclined to respond to surveys than those with less education.

The public opinion survey asked respondents to provide information on their domestic conditions, including the number of people living in the household, the number of children age 15 or less to determine the number of eligible drivers, the number of people working outside the home, and the number of vehicles owned by residents. Table 5.1 shows the most common clusters of domestic conditions for survey respondents.

Table 5.1: Domestic Conditions of Respondents

Domestic Conditions	Number	Percentage
2 people living in house No people under 15 years of age 2 people working outside house 2 vehicles	362	18.35
1 person living in house No people under 15 years of age 1 person working outside house 1 vehicle	123	6.23
3 people living in house 1 person under 15 years of age 2 people working outside house 2 vehicles	114	5.78
3-4 people living in house 2 or less people under 15 years of age 2 person working outside house 3 vehicle	101	5.12
2 people living in house No people under 15 years of age 2 people working outside house 3 vehicles	87	4.41
2 people living in house No people under 15 years of age 1 person working outside house 2 vehicles	85	4.31
4 people living in house 2 people under 15 years of age 2 people working outside house 2 vehicles	80	4.05
3-4 people living in house 1-2 people under 15 years of age 1 person working outside house 2 vehicles	79	4.00
Other/No Response	942	47.75
Total	**1973**	**100.00**

Figures 5.4 and 5.5 show the normal commute and trip routes for survey respondents. Originally, the commute route was determined by the highway corridor in which motorists were observed. This designation could then be used to measure sub-regional differences in opinion about HOV lanes. However, many respondents were observed in locations outside their normal commute routes or had commute routes that included more than one traffic observation corridor. To best analyze sub-regional differences in opinion, the commute route information was broken down into categories containing complete information on the commute route and other travel during peak hours. The major freeways located within the Puget Sound region were divided into ten corridors.

1)	I-5 North	6)	I-405
2)	I-5 Central	7)	SR 16
3)	I-5 South	8)	SR 167
4)	I-90	9)	SR 410
5)	SR 520	10)	SR 512

The percentage given represents the use of a given corridor by the survey population and not the percent of total use for freeway corridors within the Puget Sound region.

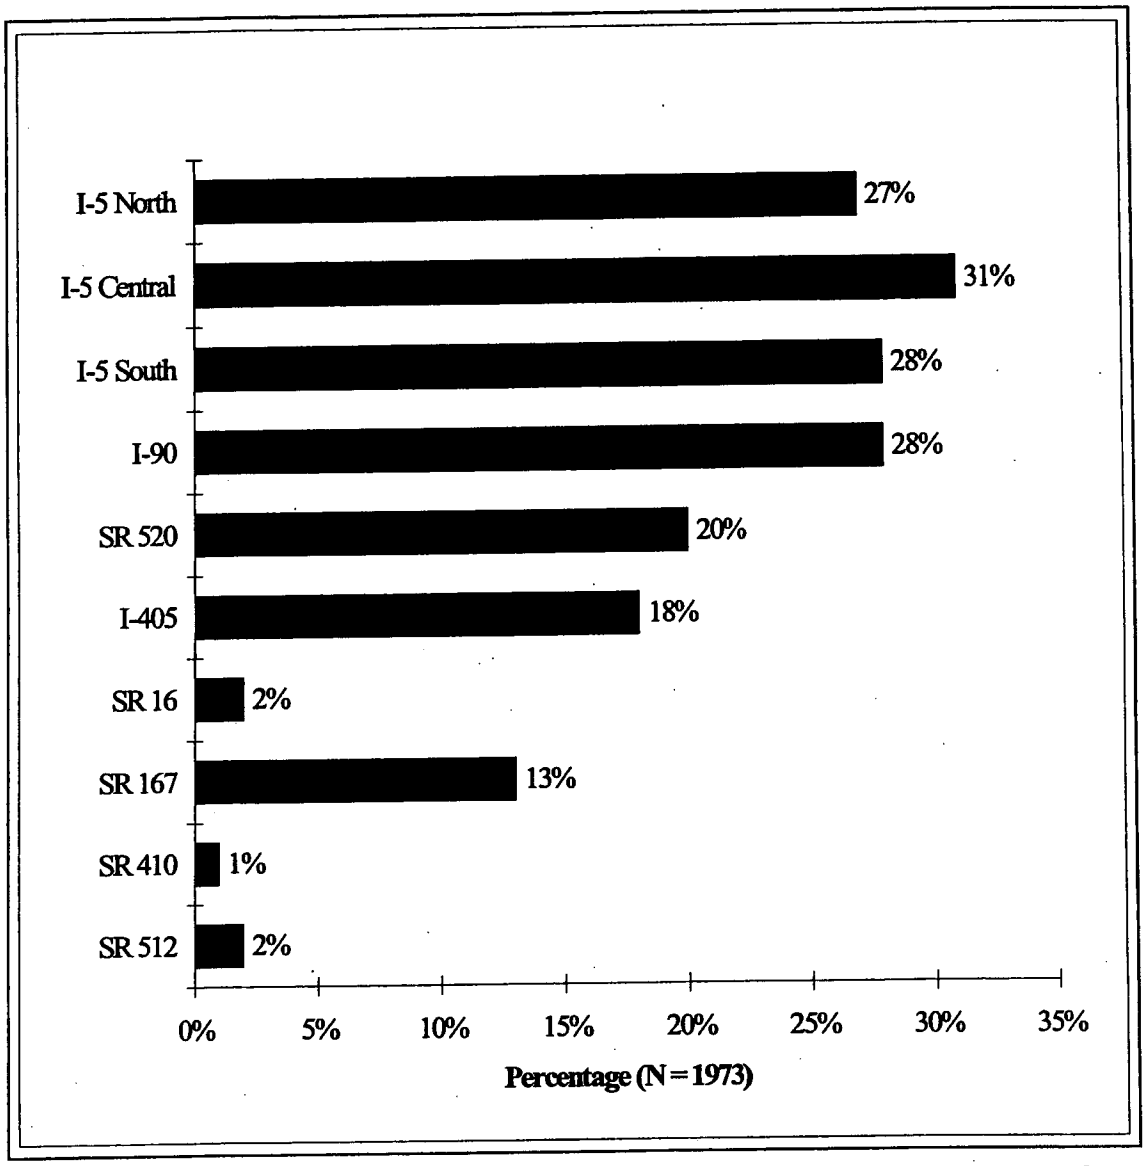

Figure 5.4 Normal Commute Route: This chart represents the true percentage of usage of the desired commute corridor.

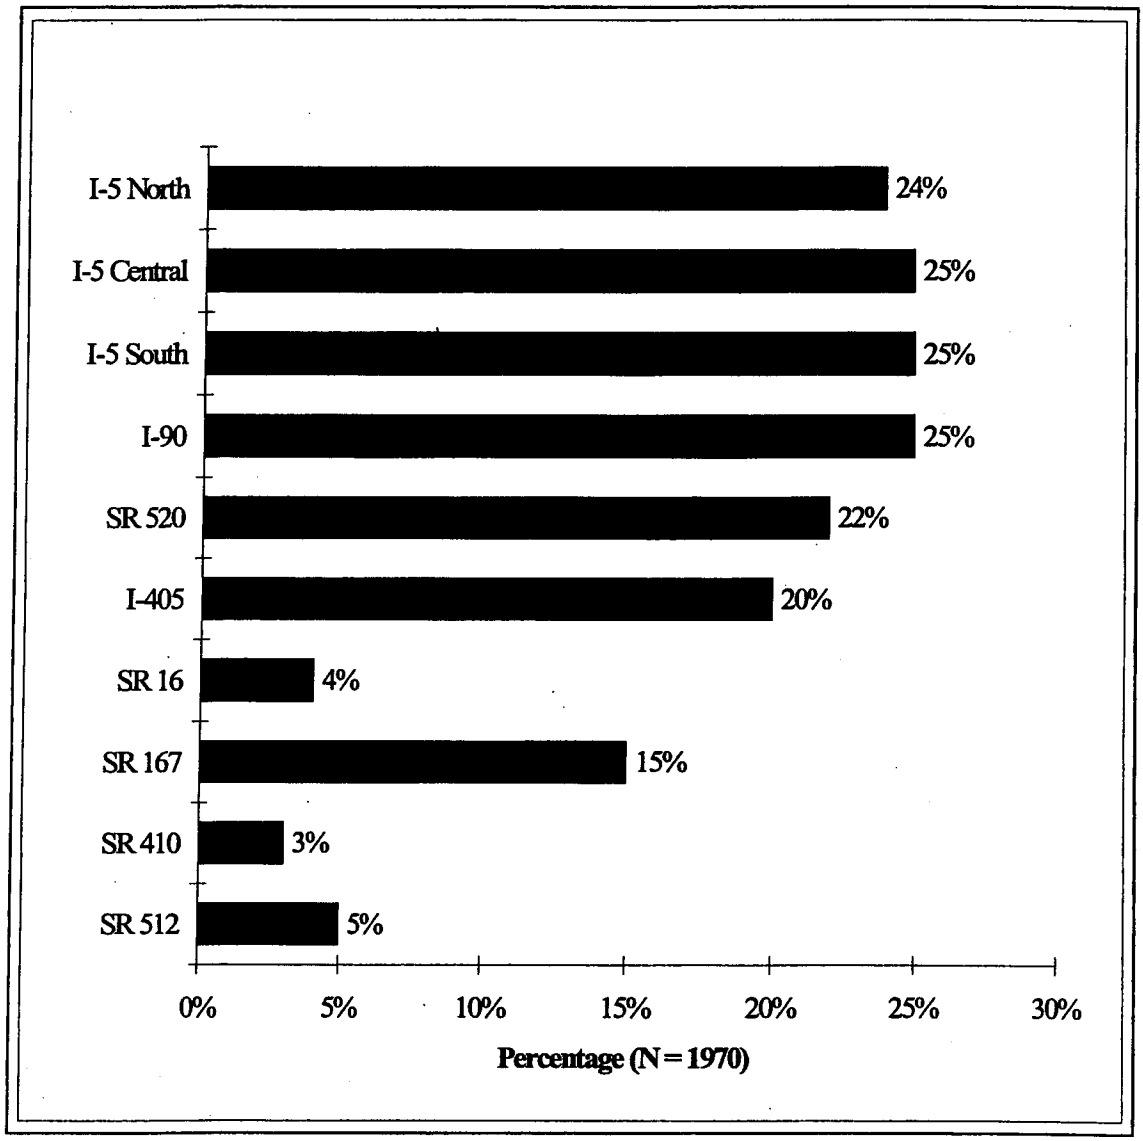

Figure 5.5 Normal Trip Route: Again, this chart represents the true percentage of usage of the desired commute corridor.

TRAVELER COMMUTE TRIP

One of the controls for classifying survey responses is commute mode. Respondents' commute modes were determined visually by an observer during the peak hour counting sessions. Vehicles were selected from both the HOV lanes and general purpose lanes at random. A vehicle's license plate was then recorded, sent to the Department of Motor Vehicles, and returned with the registered owner's name and address. Unfortunately, the observed driver is not necessarily the registered owner, so asking the respondent to specify the commute mode of choice helped to avoid any confusion on this point.

Figure 5.6 shows the actual commute modes of survey respondents. For the purposes of later data analysis, the 2 Person Carpool, 3+ Person Carpool, Bus, Vanpool, and Motorcycle responses are combined into an HOV category. Motorcycles are added to the HOV category because these vehicles are allowed to use the HOV lanes.

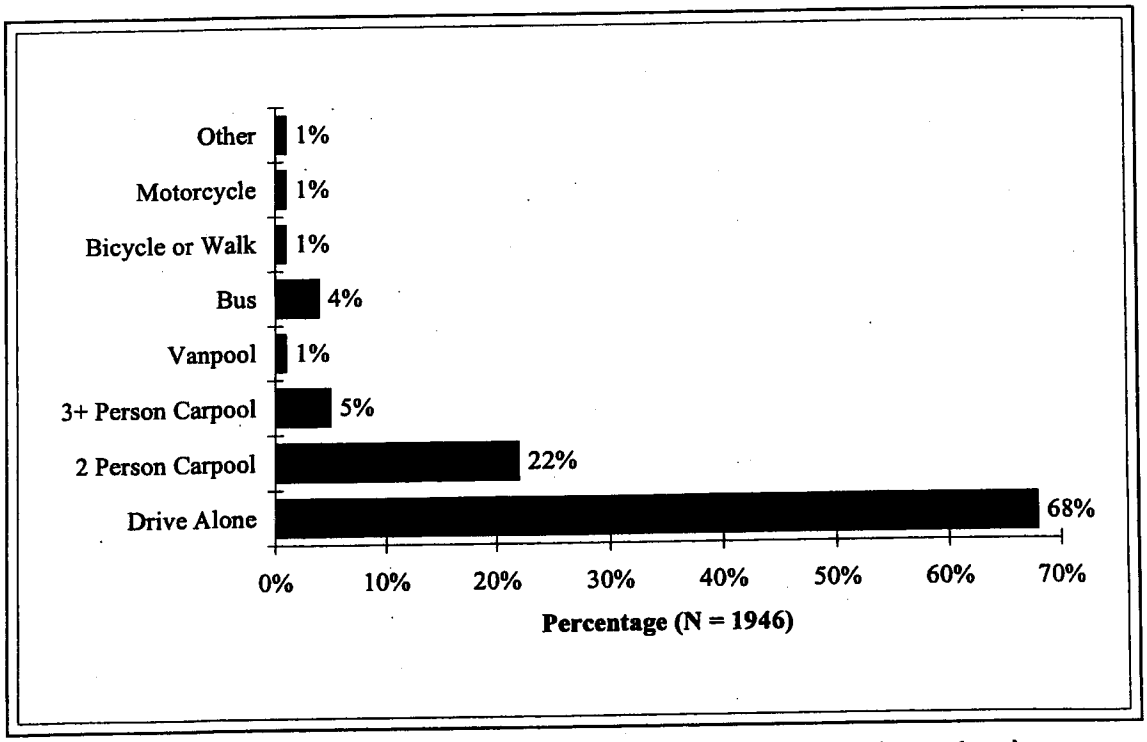

Figure 5.6: Commute Mode: SOVs far outweigh those who rideshare, despite attempts to generate comparable samples of HOV and SOV drivers.

Figures 5.7 and 5.8 provide information on past use of HOV lanes. Respondents were asked to indicate which HOV lanes they have used and their usual driving mode while utilizing them. The total of the percentages exceeds 100 percent because respondents were asked to indicate all options that applied to their past use of HOV lanes; therefore, an individual might have used HOV lanes in more than one mode and on more than one of the designated highway corridors.

Trends in HOV commute mode have remained fairly consistent, dominated by 2 and 3+ carpools. The percentage of respondents along all the observation corridors who have used HOV lanes also remained fairly consistent. These mode choices are influenced by a variety of factors, one being the pressure of congestion levels. It is possible that commuters are responding to congestion pressures and subsequently have altered their commute mode for a more favorable option, namely HOV lanes.

It should be understood that these opinions are compiled from the responses of returned surveys. Because of the random nature of the mailing and those returning the surveys, conclusions drawn from this data should not be considered completely representative of the driving population; rather they should be considered and further investigated in a more analytical fashion.

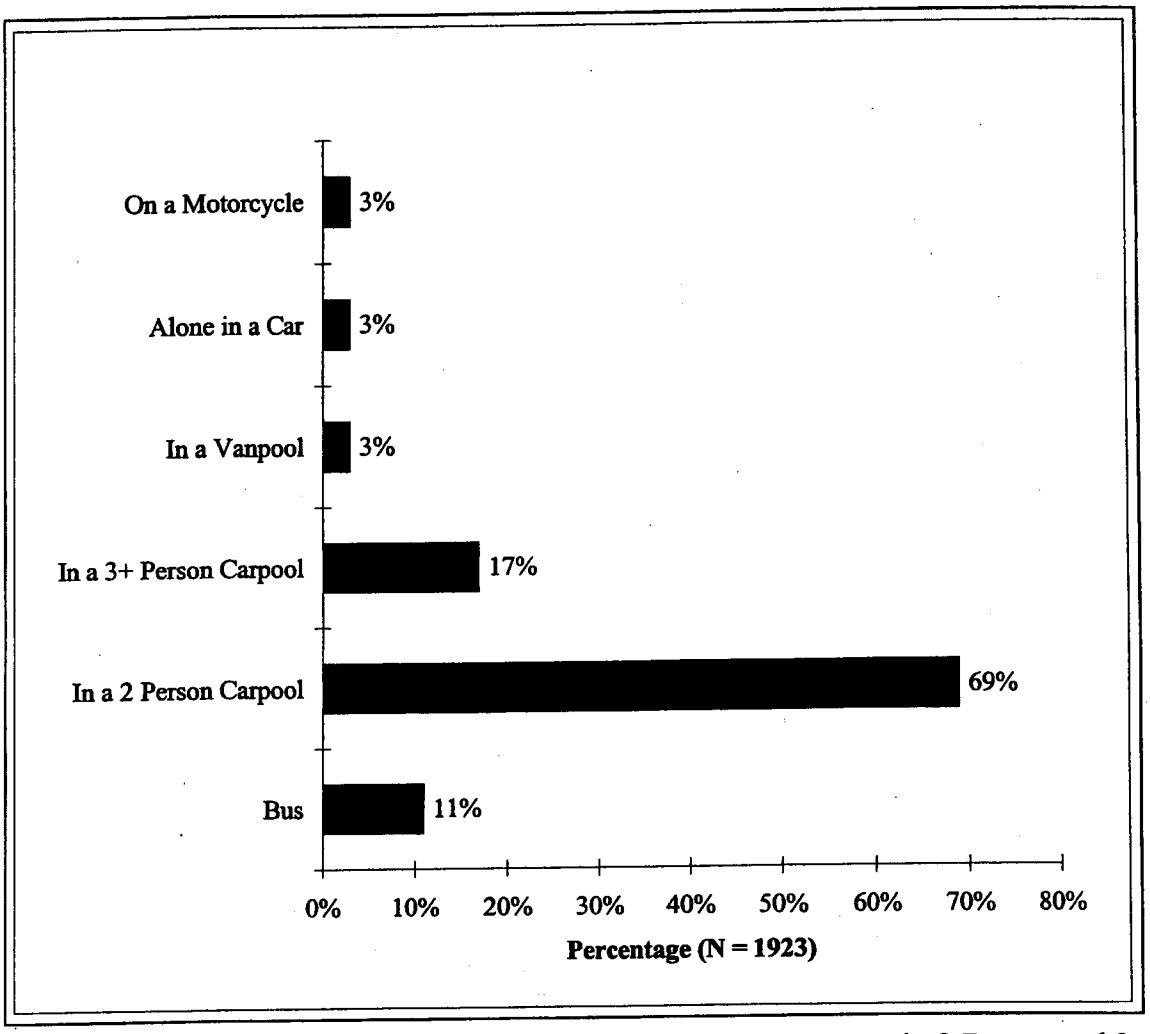

Figure 5.7 Past Use of HOV Lanes: The high response percentage in 2-Person and 3+ Person carpools could suggest that HOV lanes are popular during the work week when employees commute together. There was a sharp increase in the percentage of respondents selecting the 2 person carpool option (+31 %) when compared with previously recorded levels. Because of the wording of this question (ever use vs. usually use), the class percentages are higher than those of Figure 5.6.

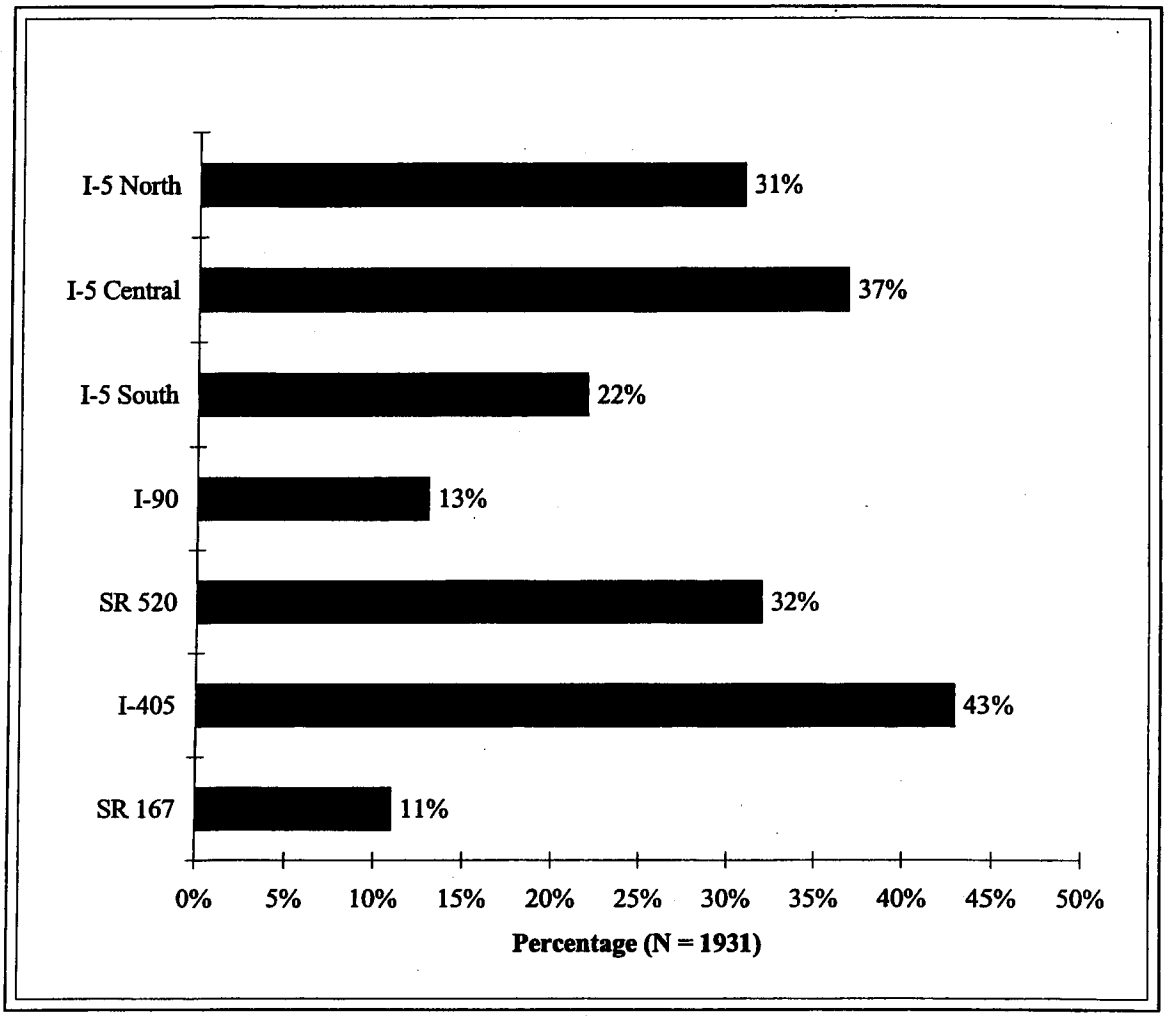

Figure 5.8 Past Use of HOV Lane Corridors: Again, the frequency of drivers who have utilized HOV lanes along the I-405 corridor surpasses that of all other study corridors. This is due to fact that the I-405 corridor is not divided into segments as is the I-5 corridor.

Figures 5.9 and 5.10 show the percentages of respondents who have, in the past, qualified to use the HOV lane but chose not to use the lanes and a list of reasons for this choice. Data for Figure 5.10 represent single instances in which respondents chose not to use HOV lanes. Respondents were asked to check all conditions that have kept them from using HOV lanes when they have been to eligible use them. These questions were modified in February 1994 to limit the time of consideration to the peak-hour periods only, but this modification had little effect on the results. As the HOV lane system is completed, it will be interesting to track opinion on these questions to see whether the travel time savings provided by longer HOV lanes attract more carpoolers.

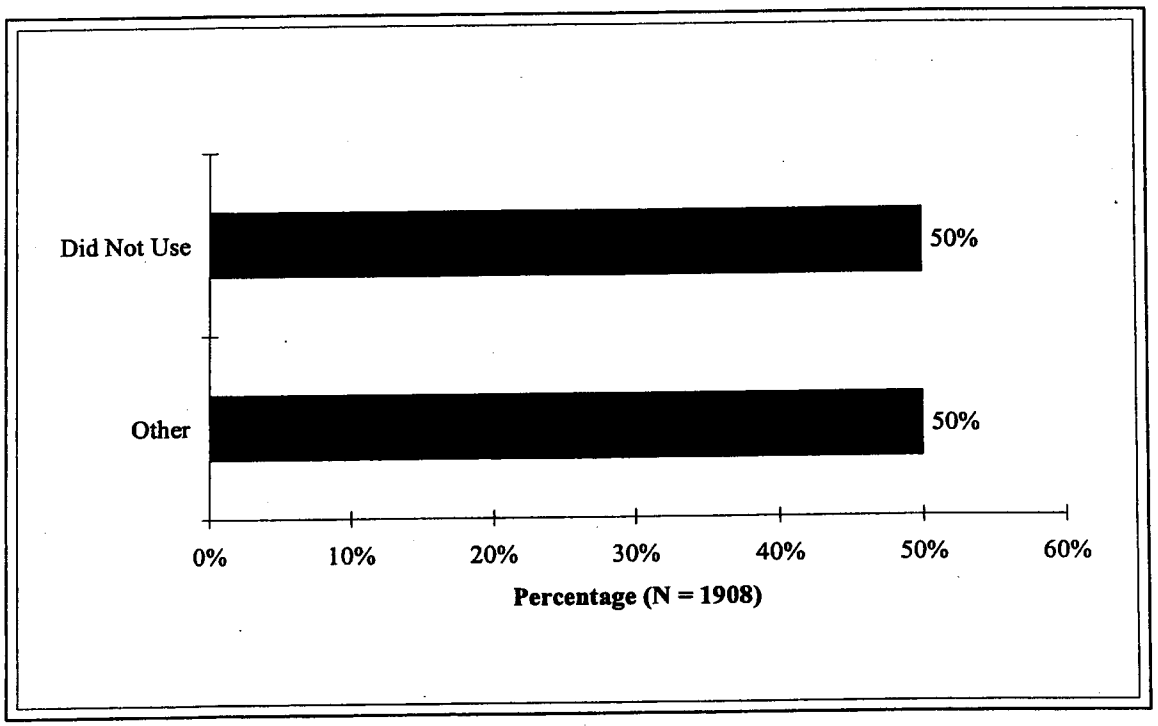

Figure 5.9 Qualified for HOV Lane Use: A significant number of respondents chose not to utilize HOV lanes even when vehicle occupancy requirements were met. By addressing the reasons for this choice we may be able to increase use of HOV lanes and facilitate a greater level of service for all lanes in general.

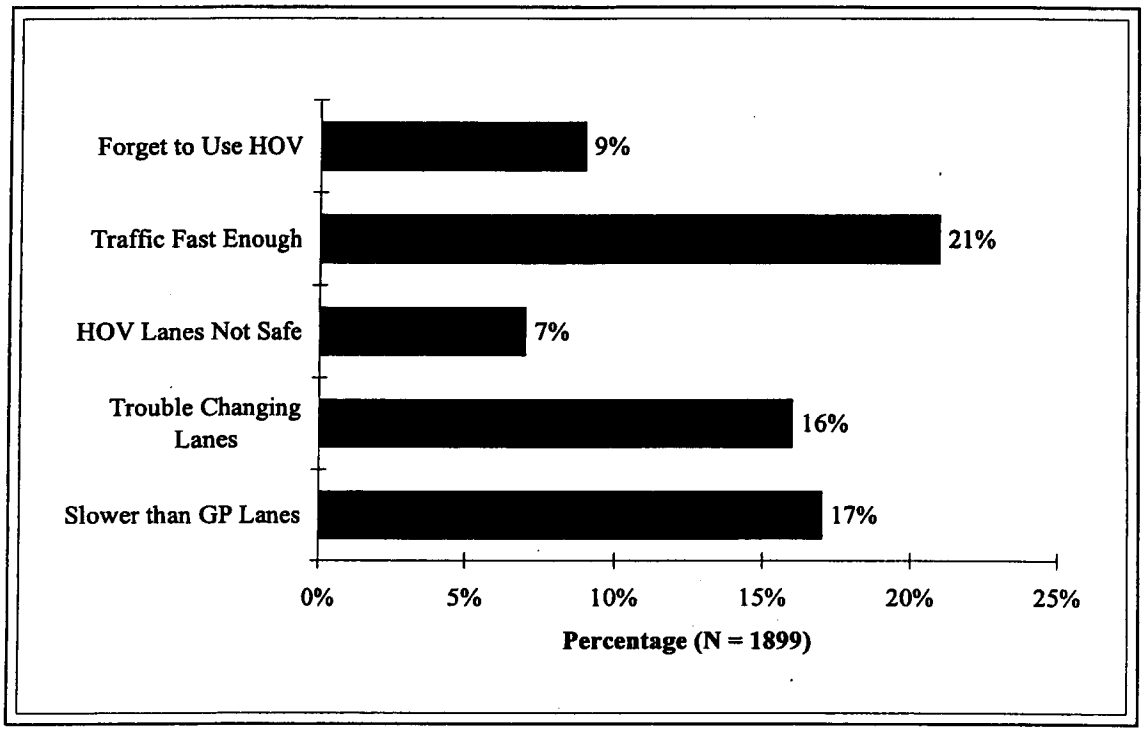

Figure 5.10 Reasons HOV Lanes were Not Used: Again, the selection "Traffic Fast Enough" predominates this question. First thought to be a result of the question's wording, changes made to the survey have not produced any noticeable changes in the class percentages. Obviously, when traffic moves freely, there is no compelling reason for an HOV driver to use the HOV lanes.

TRAVELER OPINIONS

Figure 5.11 shows the combined HOV and SOV responses for this set of options designed to enhance the attractiveness of the HOV lanes. This question was altered in October 1995 by removing the "2+ carpool for all HOV lanes" option and adding a new "inside access ramp" option. This question was revised further in November 1995. The "Connect HOV lanes" option was replaced with an "Increased bus service" option. In addition, the "Put HOV lanes on the right" option was clarified by giving respondents the choice of either "inside" or "outside" HOV lanes as options (Figure 5.13 & Figure 5.14). Because respondents were asked to check three of seven options, the number of responses exceeds the number of overall survey responses. The distribution of responses remained consistent with that of the previous survey period, and the trends found earlier continue to exist.

The data presented in Figure 5.11 are broken down by commute mode in Figures 5.12 through 5.19. The revision to the option related to HOV lane alignment (inside vs. outside) shows respondents favoring inside HOV lanes (41%) opposed to outside HOV lanes (19%). The new "Increased bus service" option also ranked highly among respondents. A p-value, representing statistical significance, is also provided for each question. A p-value of .05 or less represents statistically significant differences of opinion between HOV and SOV groups.

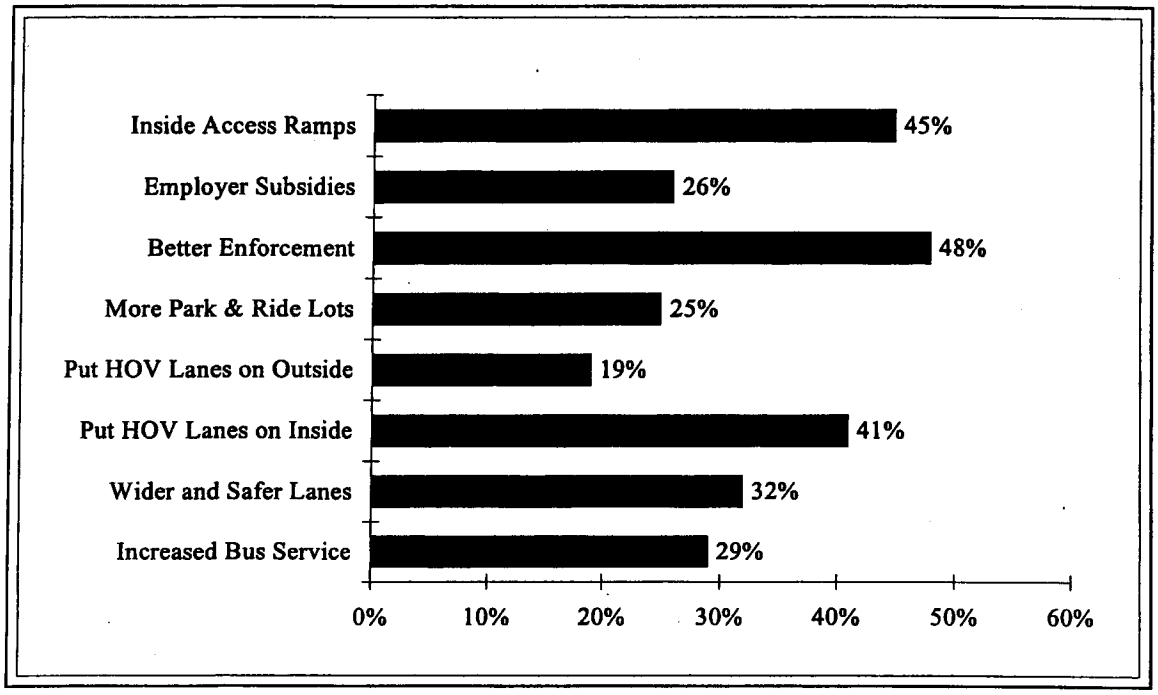

Figure 5.11 Options to Improve HOV Lane Usage: Enforcement concerns and access issues appear to outweigh transportation demand management measures such as employer subsidies for ridesharing and additional Park & Ride lots. The issue of HOV lane configuration (right side vs. left side) is explored further in Figure 5.13 & Figure 5.14.

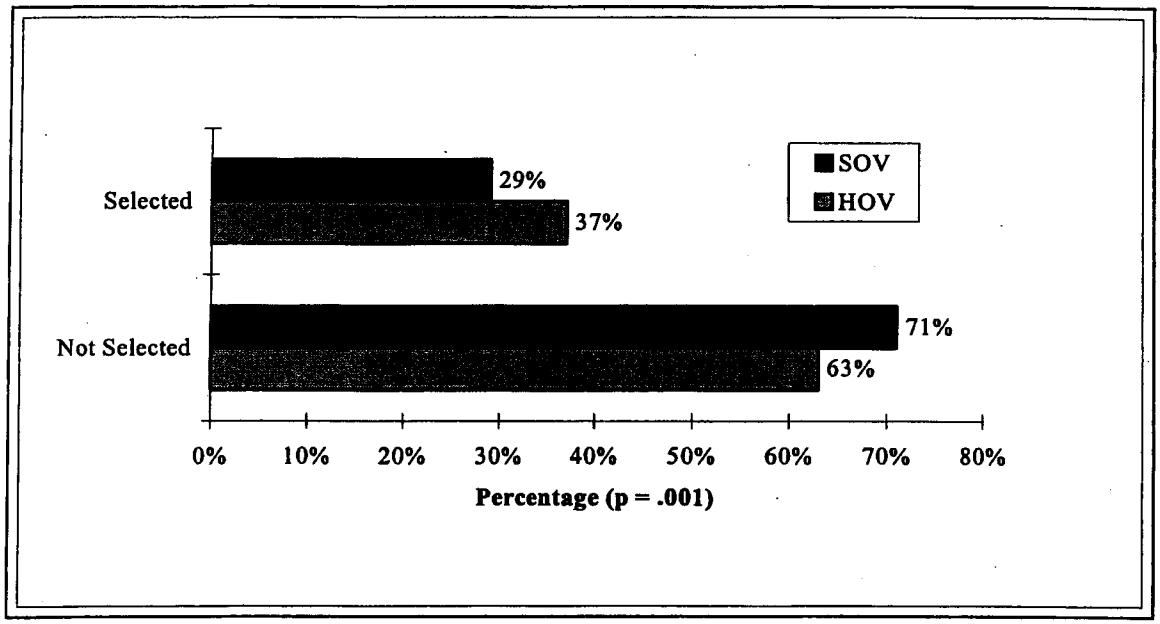

Figure 5.12 Wider and Safer Lanes: This option continues to gain support with both groups of drivers and is expected to rise in response to increased levels of congestion. The marginal difference between groups may be due to carpoolers having more experience with using HOV lanes.

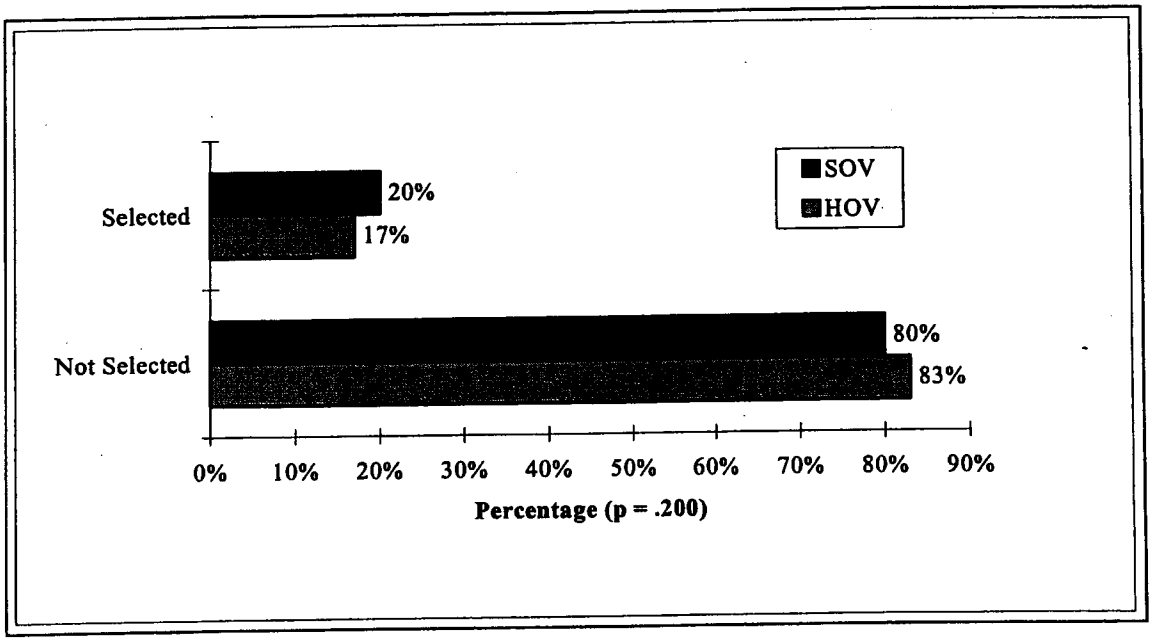

Figure 5.13 HOV Lanes on Outside of Freeway: (See text below)

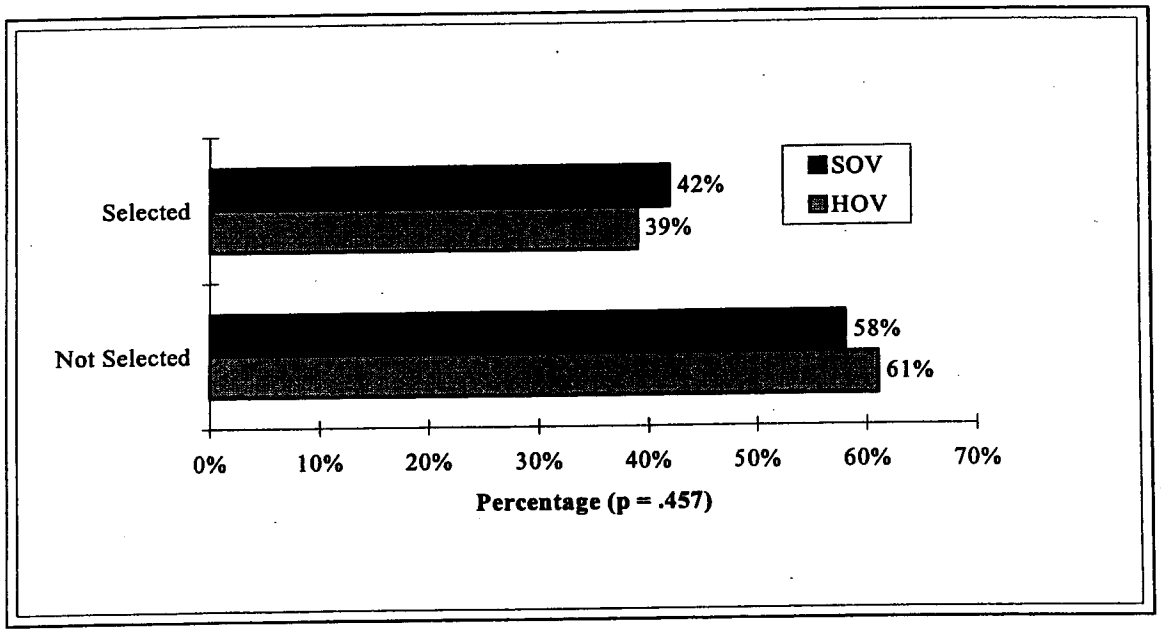

Figure 5.14 HOV Lanes on Inside of Freeway: Respondents have clearly favored *inside* HOV lanes by a two to one margin. Please note that there is a relatively high p-value is due to the difference of opinion between the two groups.

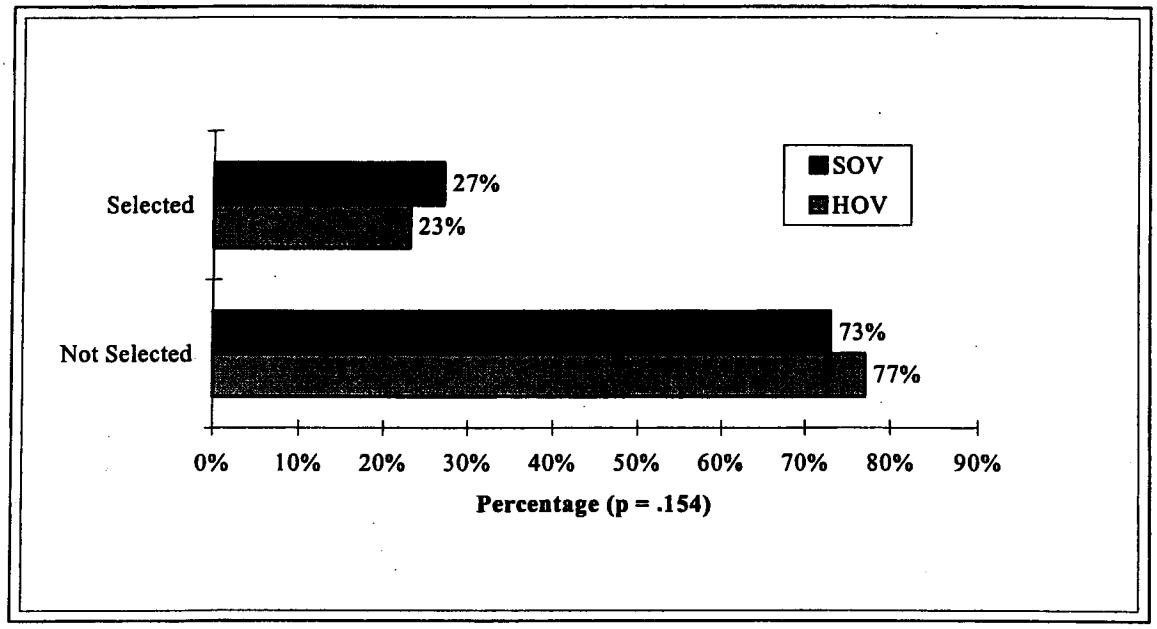

Figure 5.15 Park & Ride Lots Near Freeway Entrances and Exits: Support for the option has remained relatively unchanged, with SOV drivers showing slightly more support than their ridesharing counterparts. This may reflect the idea that Park & Ride lots are not as much places to assemble carpools as they are links to bus service.

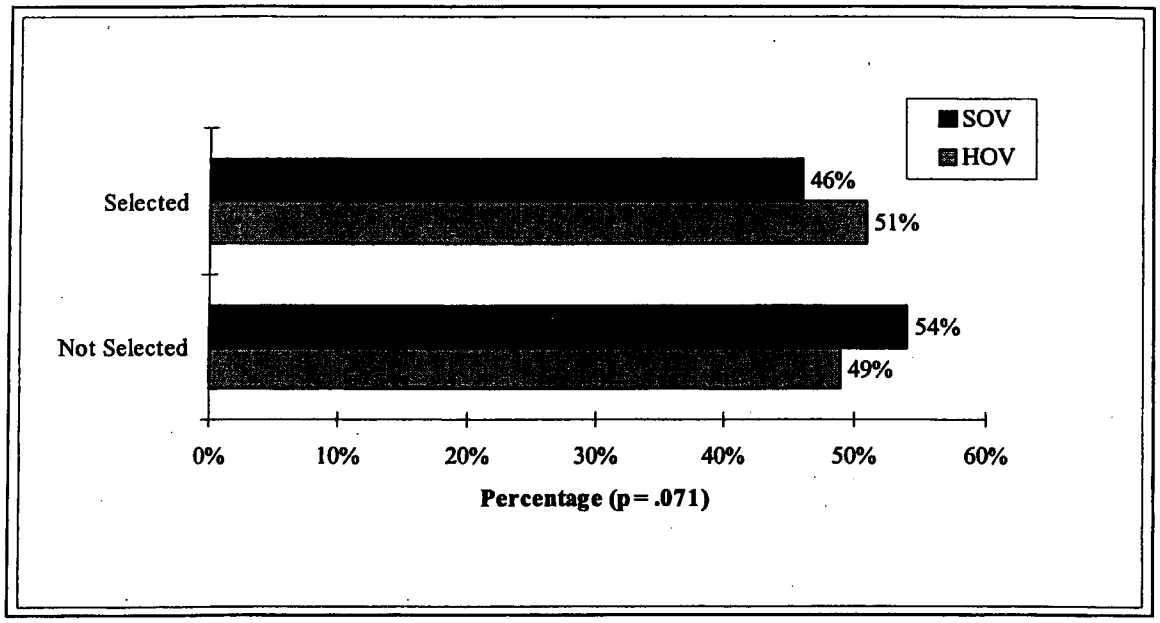

Figure 5.16 Better Police Enforcement Against Violators: Both groups appear sensitive to violations of the HOV system when others are observed abusing this special privilege.

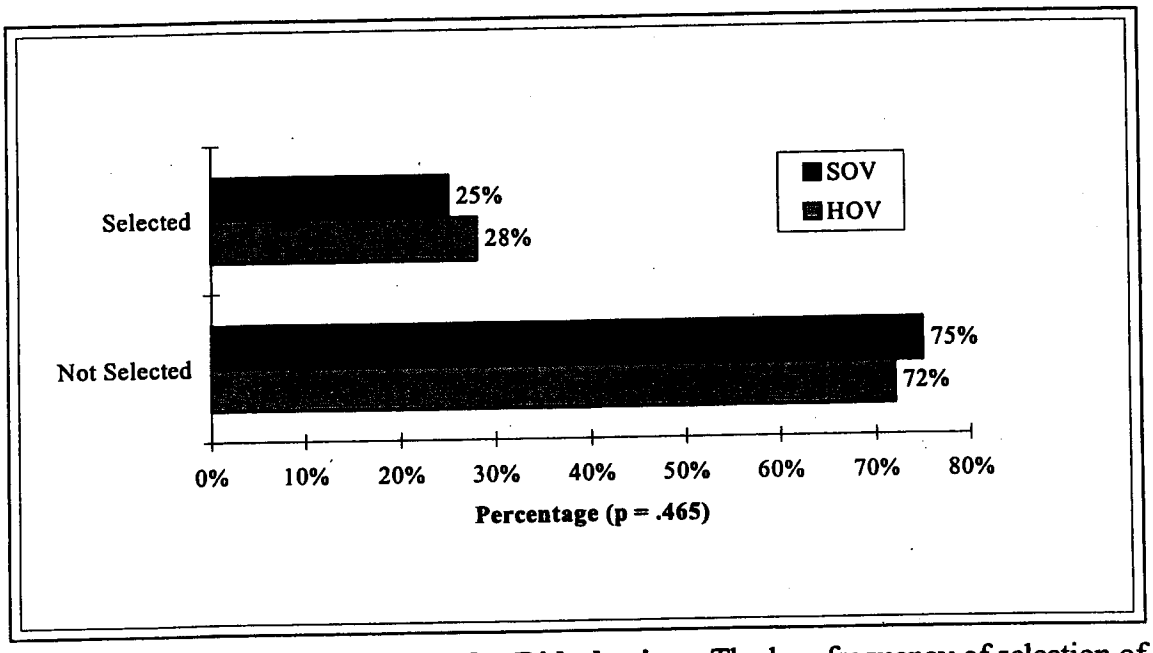

Figure 5.17 Employer Subsidies for Ridesharing: The low frequency of selection of this option among both groups may indicate that drivers do not feel that rideshare incentives are secondary to enforcement concerns and access issues.

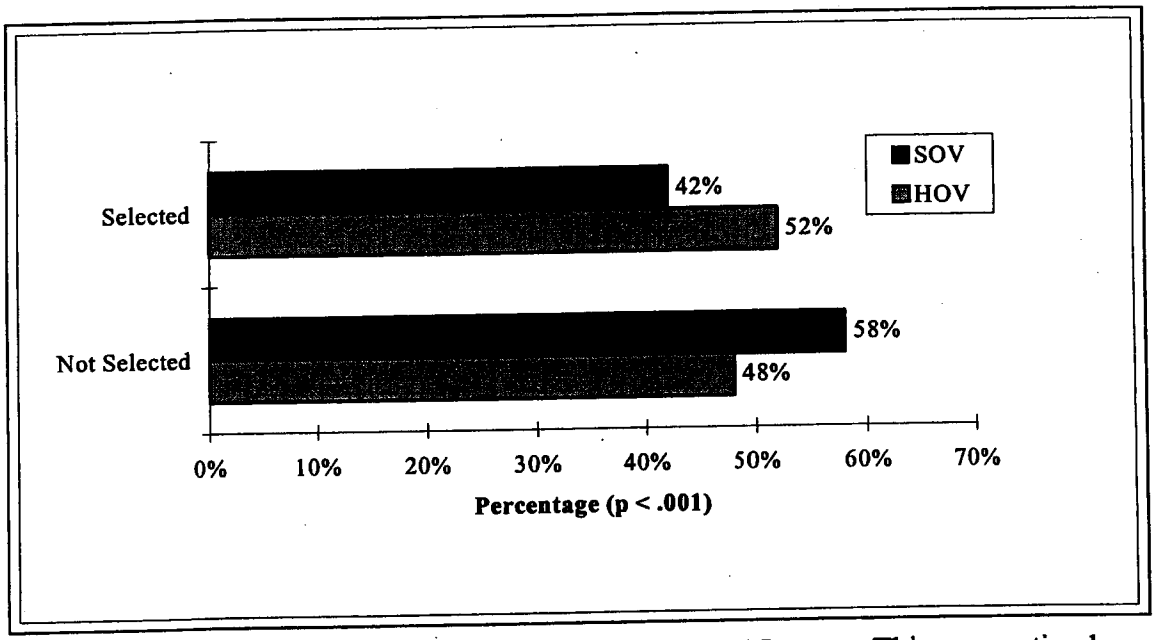

Figure 5.18 Construct Access Ramps for Inside HOV Lanes: This new option has faired well, ranking second overall in support among survey respondents. This favorable response may be due to the public's strong desire to continue expansion of the freeways to improve efficiency and lane capacity.

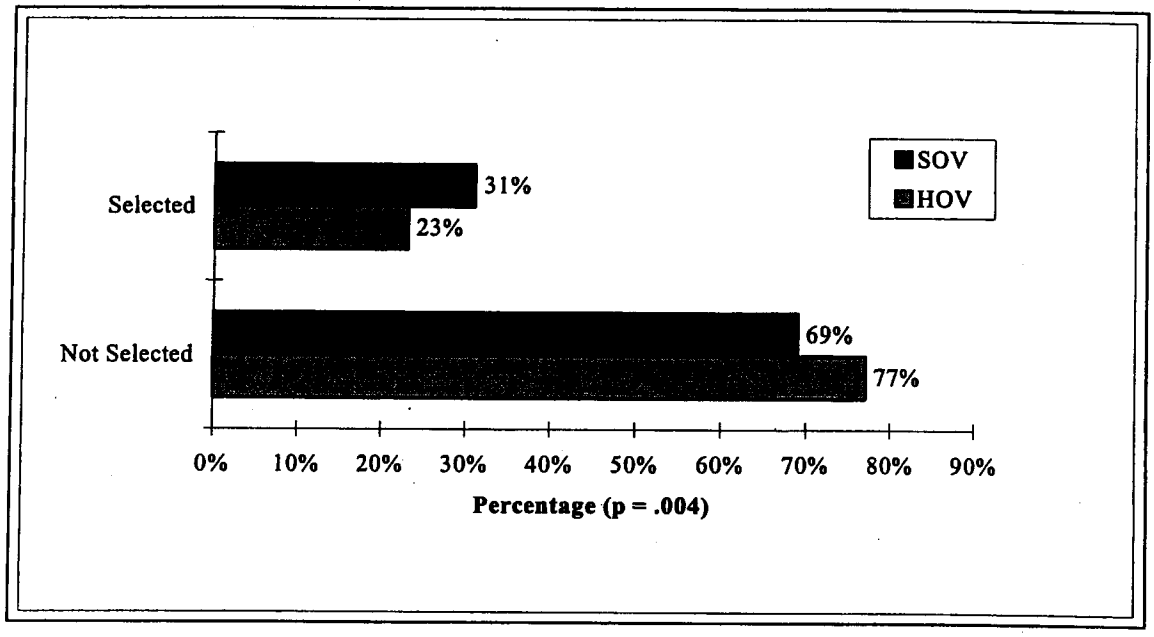

Figure 5.19 Increased Frequency of Bus Service: This option ranked highest among the TDM measures included with this question. However, like the "Employer Subsidies" and "Park & Ride lots" options, its overall priority did not compare with issues related to HOV lane access, enforcement, and safety.

OPINIONS ON VARIOUS HOV LANE ISSUES

Figures 5.20 through 5.32 present data from questions about motorists' opinions on a variety of issues related to HOV lane use and effectiveness. The responses are broken down by normal commute mode and by the degree to which respondents agree with individual assertions. Sample sizes for both HOV and SOV groups are provided for each question. The exact wording of each question is provided in the figure titles.

It is important to note that in most cases, both HOV and SOV drivers tend to share the same basic opinions on issues related to HOV lane effectiveness. While both groups tend to agree in general, the differences in opinion among HOV and SOV drivers are frequently based on the degree of support for or opposition to a particular issue. These issues are accompanied by high p-values, which are based solely on the significance of the difference in opinion between the two groups. The most notable exception to this trend is when an issue concerns mode choice and the impact of HOV lanes on congestion reduction.

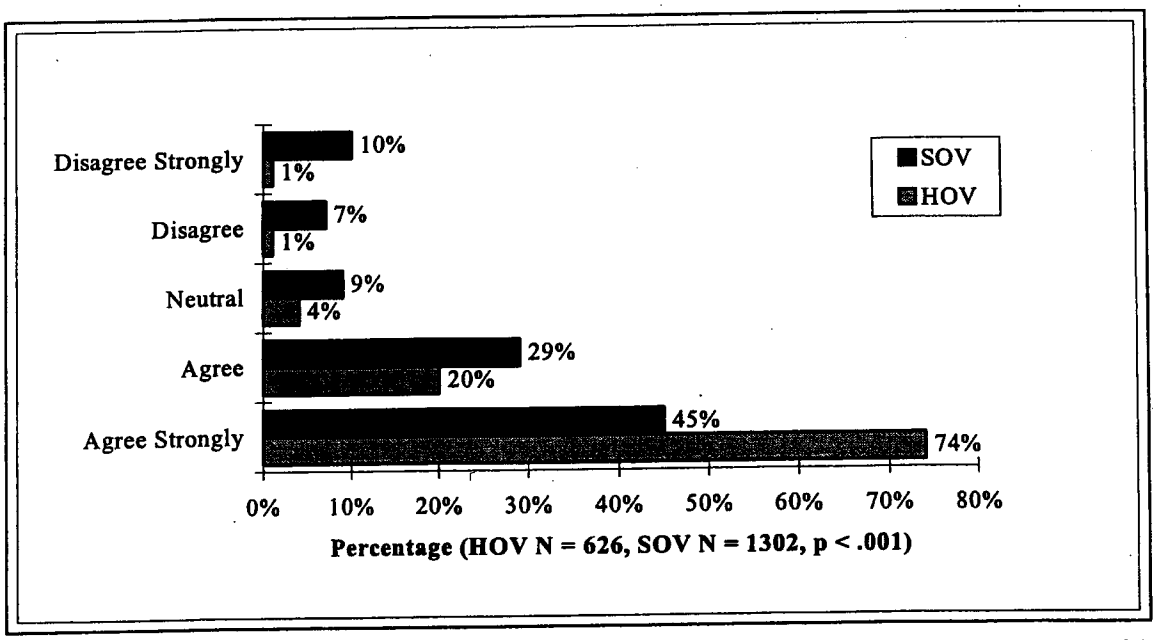

Figure 5.20 HOV Lanes are a Good Idea: Overall, 80 percent of drivers favor the idea of HOV lanes. Support for HOV lanes continues to be high among both SOV and HOV drivers, but support among SOV commuters has been showing signs of meager decline.

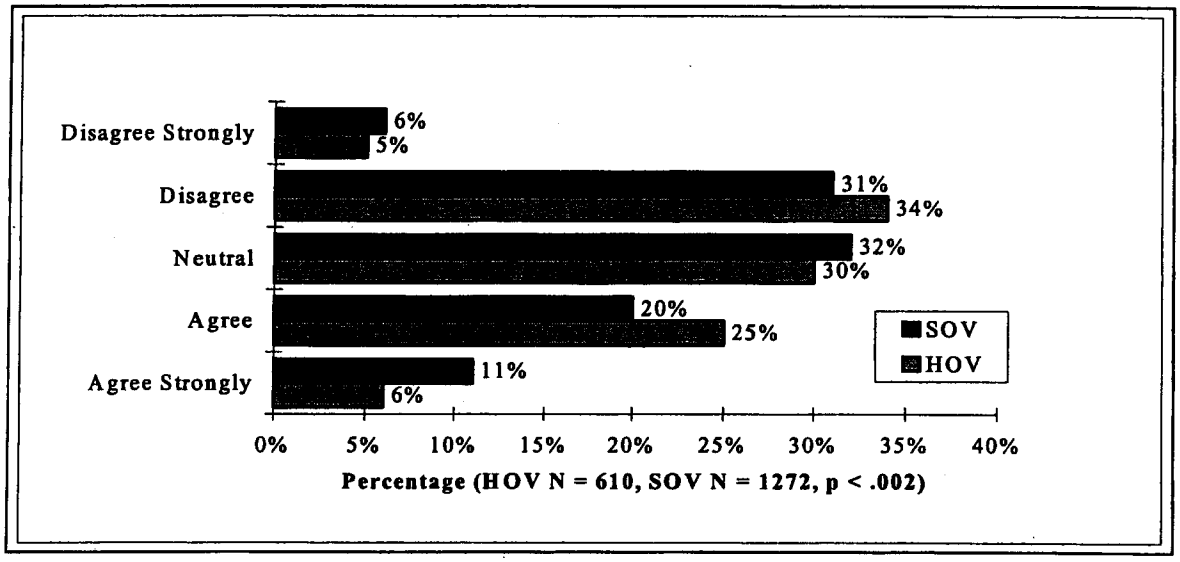

Figure 5.21 Vehicles Dart In and Out of HOV Lanes Too Often for the Lanes to be Safe: The opinions of both HOV and SOV drivers are similar on this issue. When the survey population is examined as a whole, opinion on this topic is neutral to slight disagreement. A divergence in opinion between groups is expected as congestion levels increase along the region's freeway system.

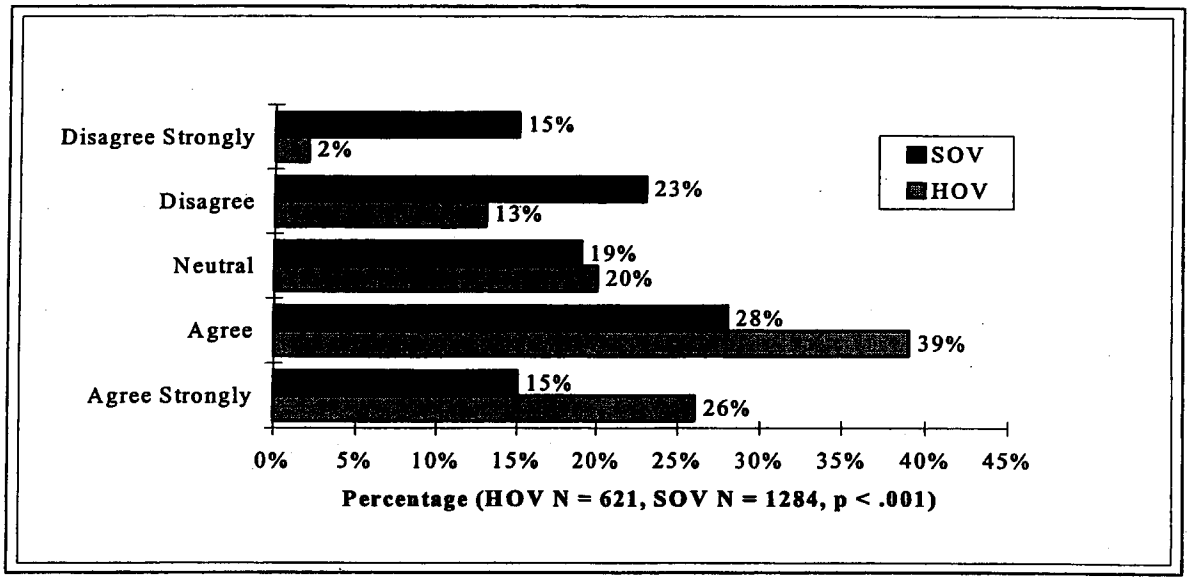

Figure 5.22 HOV Lanes Help Save All Commuters a Lot of Time: A highly significant difference of opinion on the travel time issue exists between the two groups. As expected, SOV user sentiment tends to be more negative as they are forced to wait in congestion bottlenecks during the peak commute period. HOV users express an inflated sense of travel time savings and may not be as sympathetic to time lost by their SOV counterparts.

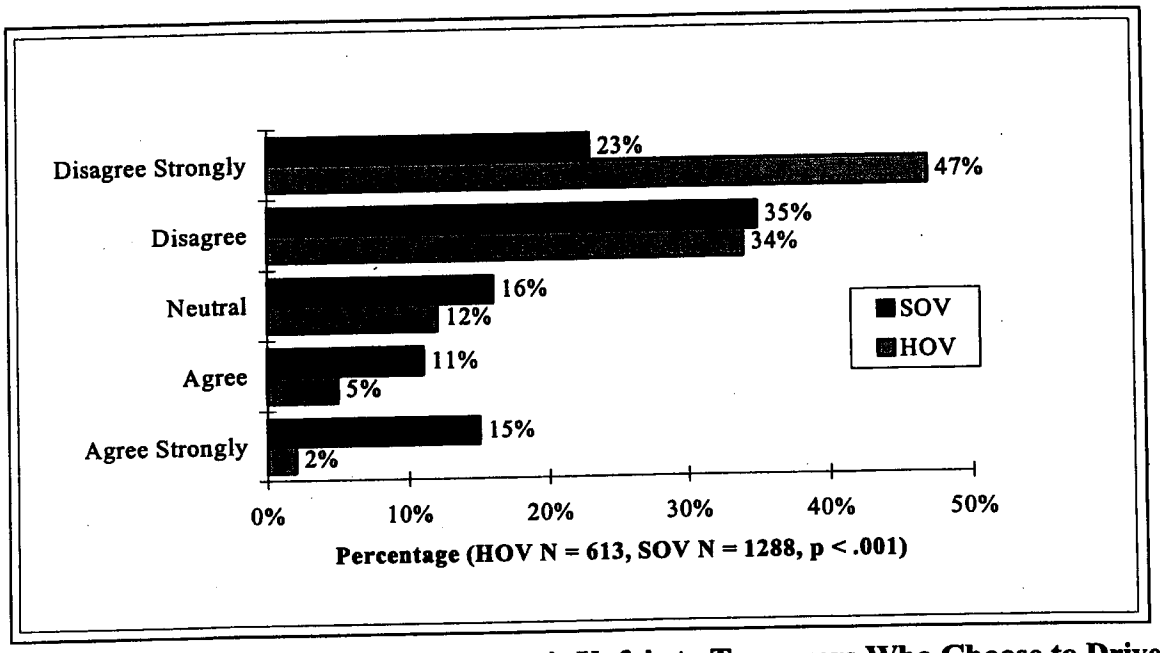

Figure 5.23 Constructing HOV Lanes is Unfair to Taxpayers Who Choose to Drive Alone: A majority of commuters still believe that HOV lanes are a fair use of taxpayers' money. Trends in the percentage of change show that the opinions of HOV groups continue to shift towards a united stance the HOV lanes are a valid use of taxpayers' money. SOV opinion remained consistent with previous survey results.

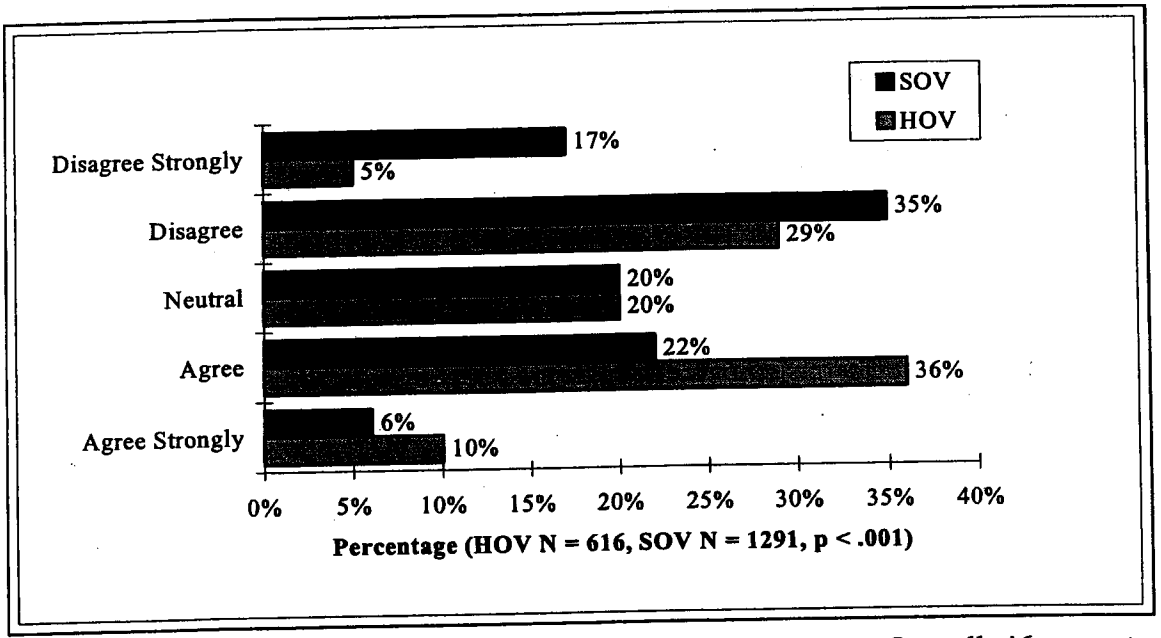

Figure 5.24 Existing HOV Lanes are Being Adequately Used: Overall, 46 percent of respondents disagreed that the HOV lanes are adequately used, 34 percent thought otherwise, and 20 percent remained neutral on this point.

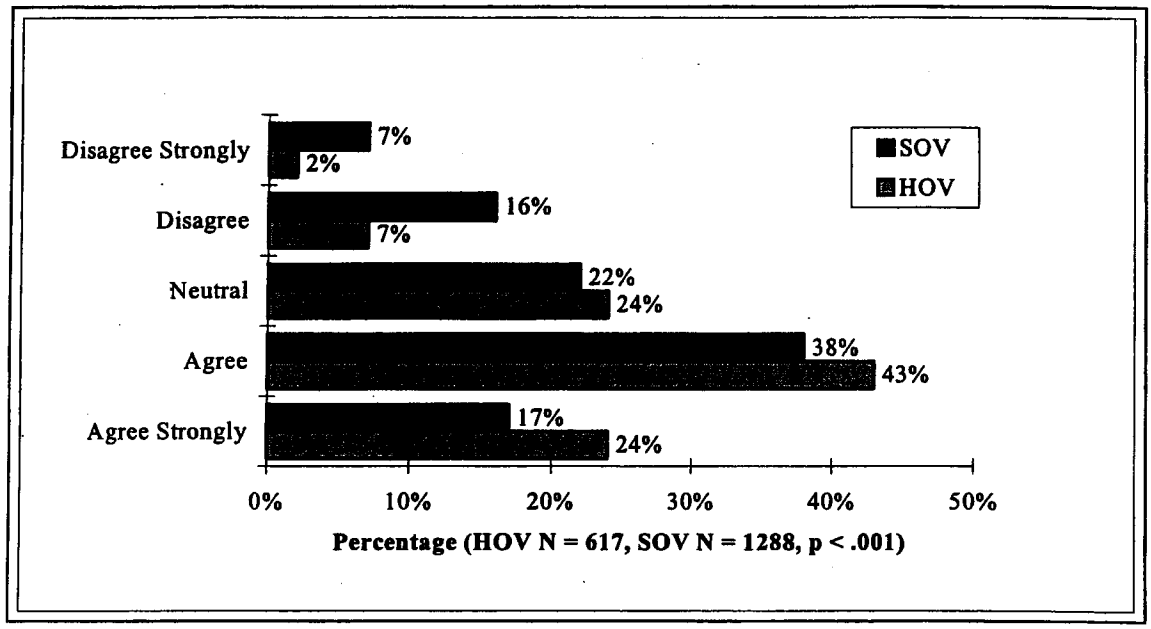

Figure 5.25 HOV Violators Commit a Serious Traffic Violation: These results suggest that SOV drivers tend to place a lower priority on HOV lane enforcement than do HOV drivers. Even so, both groups appear to resent the fact that HOV lane violators are unwilling to sit in traffic like everyone else.

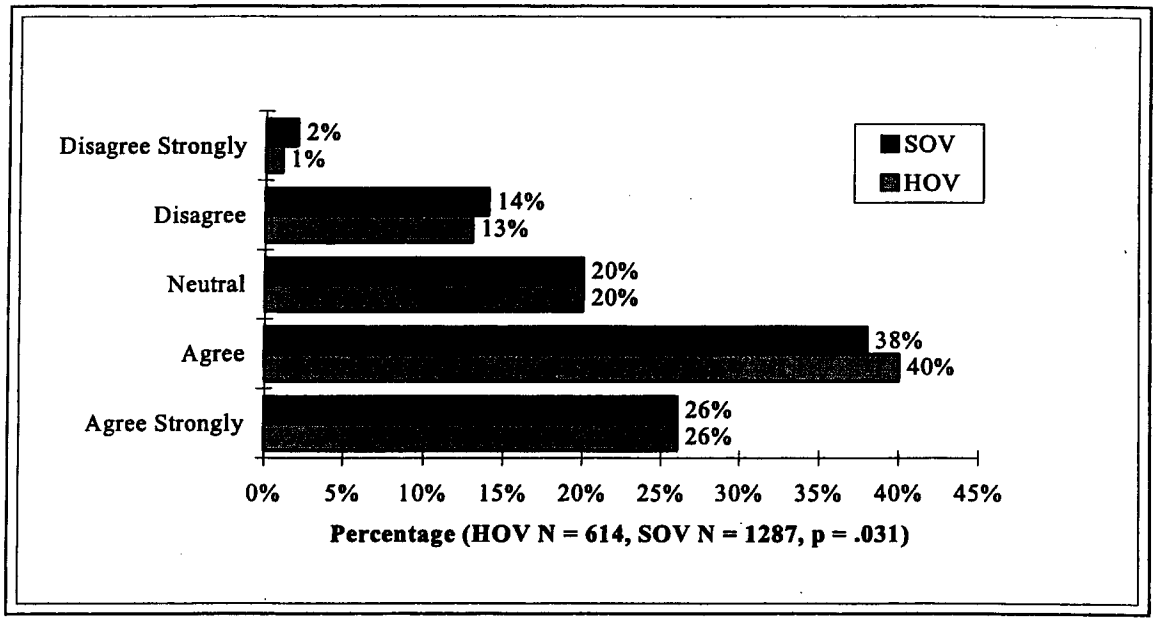

Figure 5.26 HOV Violations are Common During the Commute Hours: Overall, 64 percent of respondents agreed that violations are common during the commute hours. This may be why the option "Better Enforcement" was selected the best option for increasing the attractiveness of HOV lanes. (Figure 5.11)

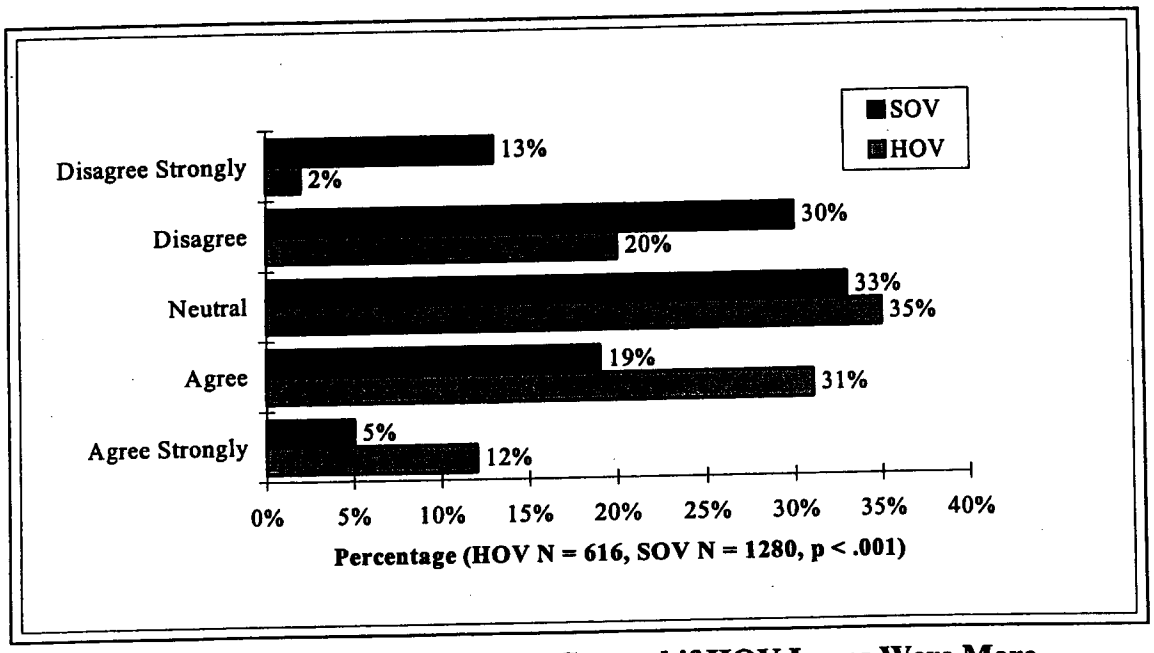

Figure 5.27 Many More People Would Carpool if HOV Lanes Were More Widespread: Opinions have remained consistent on this point, with some ambivalence among the population as a whole. There was a slight shift between the distribution of each group. Since the previous survey period, both types of commuters lost some assertiveness in their stance in favor of this opinion.

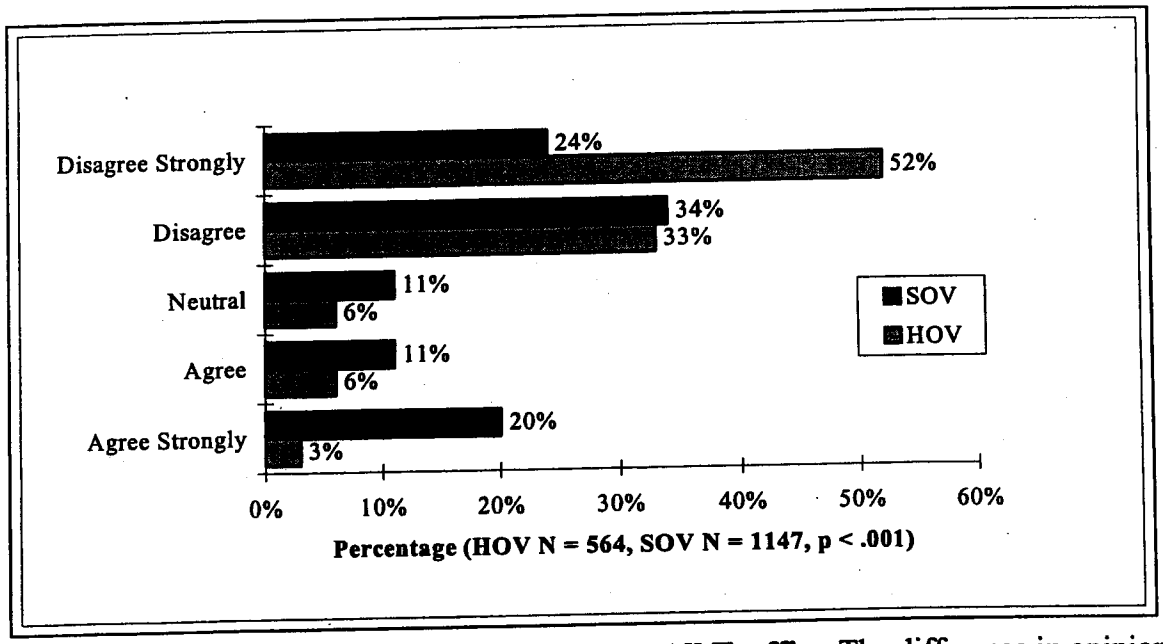

Figure 5.28 HOV Lanes Should Be Opened to All Traffic: The difference in opinion between groups on this issue remained the same compared to previous survey results.

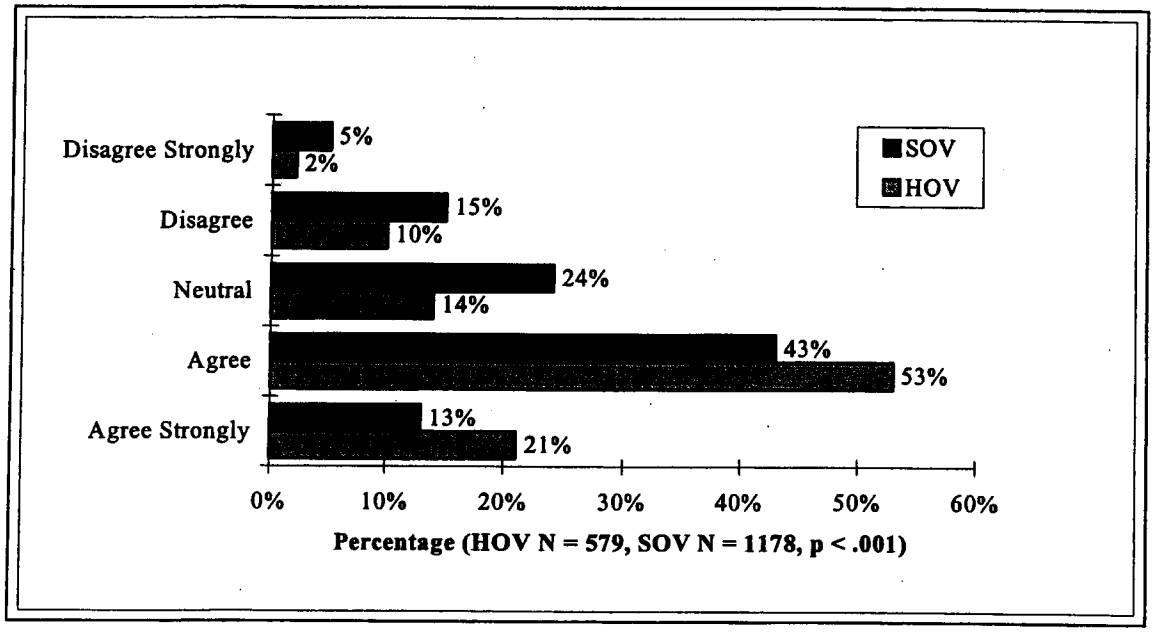

Figure 5.29 HOV Lanes are Convenient to Use: Again, both groups agree that HOV lanes are easy to use. As expected, HOV drivers are stronger supporters because of the fact that they are more familiar with the benefits and hazards of the HOV system.

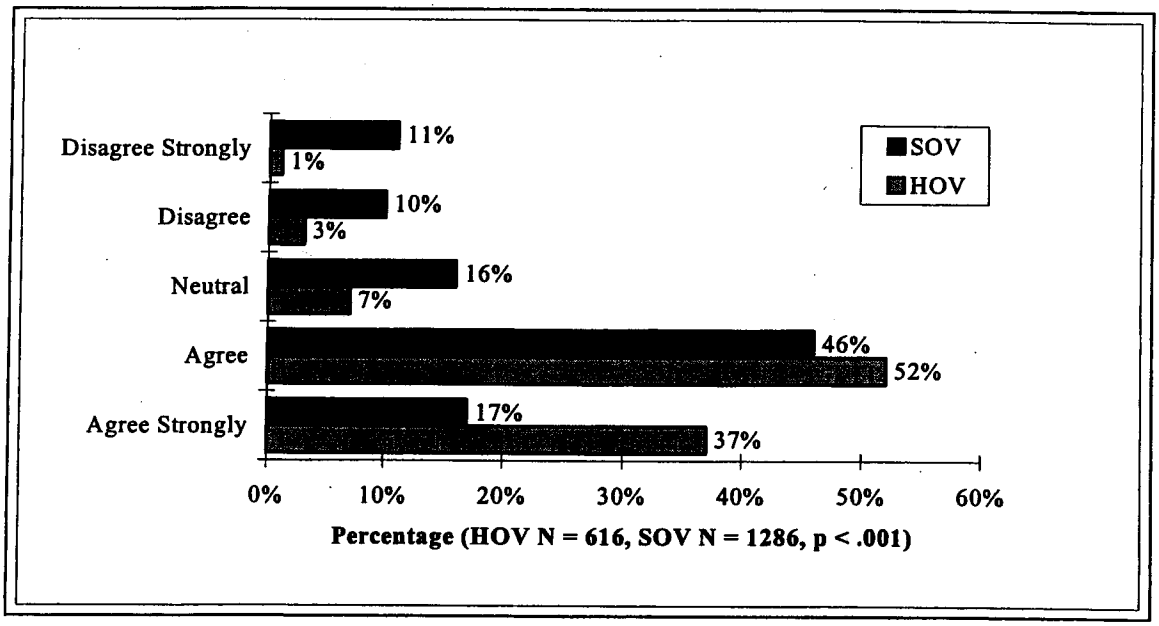

Figure 5.30 HOV Lane Construction Should Continue, in General: A majority of commuters continue to support the HOV lanes, with 71 percent in favor of this opinion.

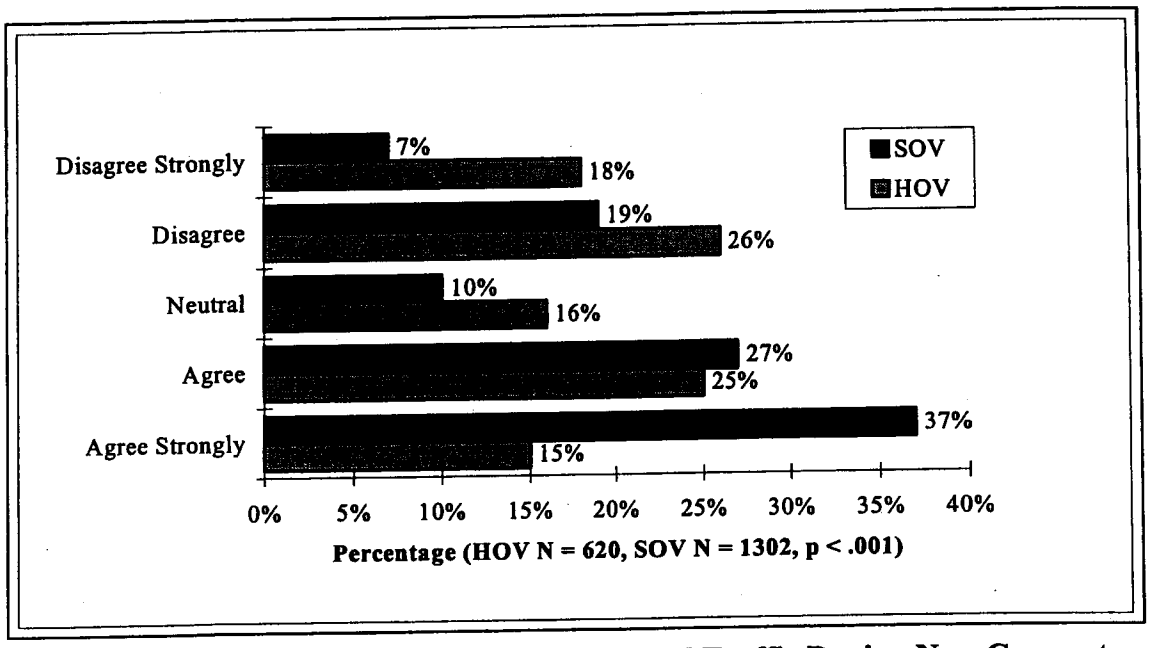

Figure 5.31 HOV Lanes Should Be Opened to All Traffic During Non-Commute Hours: Opinions on this option continue to vary widely. SOV users favor opening HOV lanes, with 64 percent agreeing; and HOV drivers remain undecided, with 40 percent agreeing and 44 percent against. Overall, HOV opinion tends towards keeping restrictions on HOV lanes at all times (A two percent increase over previous results).

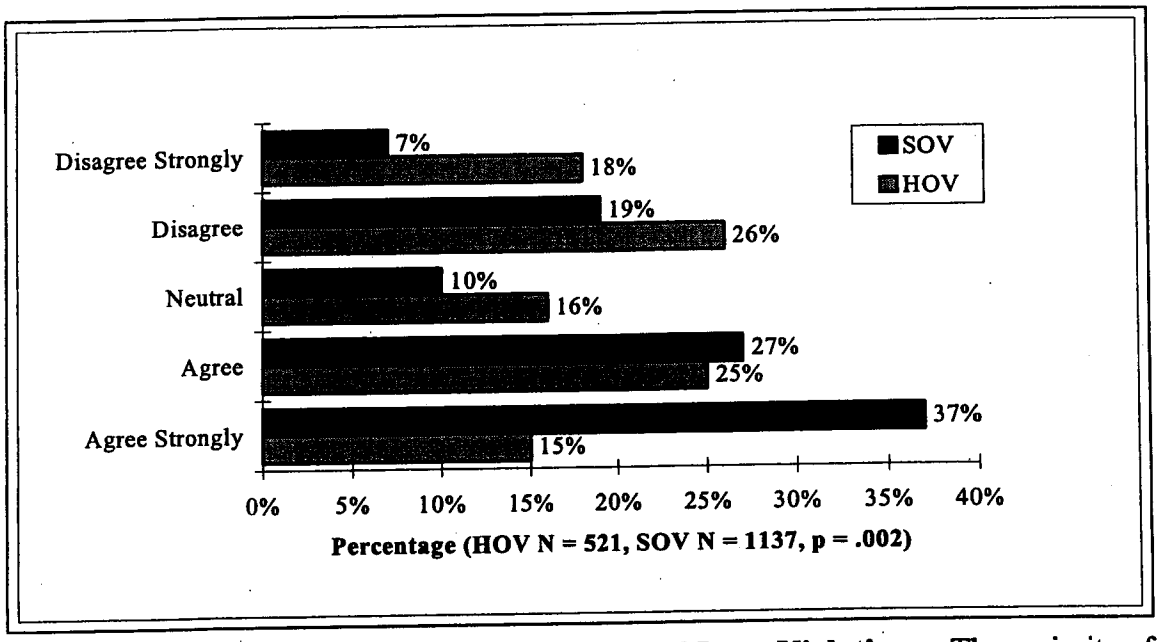

Figure 5.32 HERO Program Helps Reduce HOV Lane Violations: The majority of the survey respondents were neutral in their opinion of the HERO Program, with little difference between the two focal groups. Further public education may be needed to

provide commuters with a greater understanding of the important role 764-HERO plays in controlling HOV lane violations.

SUMMARY OF PUBLIC OPINION SURVEY RESULTS

There is strong public support for HOV lanes in general and for future HOV lane construction. Although there are differences of opinion on many issues between SOV drivers and those who rideshare, these differences do not undermine general support for HOV lanes among the entire survey population.

One sentiment evident throughout the survey was that while the public supports HOV lanes, many people feel that the lanes are not being fully utilized. The results from questions presented in Figure 5.12 through 5.32 should assist planners in selecting the HOV lane policies that will make the lanes more attractive to the public. Results from these survey questions will be valuable in assessing the desirability of these policy options.

CHAPTER SIX: SECONDARY DATA SOURCES

BUS RIDERSHIP ON HOV LANES

One goal of adding HOV lanes is to increase the use of public transit by people who normally drive alone along routes that include HOV lanes. Currently, Metro (King County), Community Transit (Snohomish County), and Pierce Transit all have bus routes that use HOV lanes. It is assumed that public transit becomes more attractive to commuters as congestion increases travel times and erodes travel time reliability. Data from Metro, Community Transit, and Pierce Transit provide the basis for measuring HOV lane effectiveness in this area.

Results from the most current public opinion survey period show that 4 percent of respondents regularly commute by bus and that 11 percent have ridden on a bus that used the HOV lane. Overall, survey respondents do not appear to support incentives to increase bus ridership on HOV lanes as much as they support options that make HOV lanes more attractive to auto users (Figure 5.11). One reason that public transit improvements are not favored as much as other methods of making HOV lane use more attractive may be that the sample generated for this study consisted primarily of auto users.

Metro Transit Ridership

Metro uses a statistical sampling method to measure ridership. Passenger counters are placed on a portion of the buses on each of Metro's runs. These passenger counters tally riders throughout the day. The passenger count samples generate a measure called the average daily maximum load. The average daily maximum load is then projected to the rest of the runs on the route. This measure is multiplied by the number of daily runs on that route to generate an average daily ridership estimate for a

given section of freeway. Table 6.1 shows the average weekday Metro ridership figures on area freeways.

Analysis of monthly ridership trends were not possible because of the sampling method used by Metro transit. Metro measures average daily maximum ridership for three trimesters of the year: Spring (February 15 through June 5), Summer (June 6 through August 28), and Fall/Winter (August 29 through February 12). Although these divisions allow analysis of seasonal changes in transit ridership, dividing the year in this way complicates the analysis of monthly ridership estimates. First, the divisions of the year are unequal. Using the average daily maximum load to determine monthly totals would inflate some monthly totals and depress others. Second, the accuracy of this measure is based partly on aggregation of the numbers. Disaggregation would reduce the accuracy of the estimation method. However, as an overall estimate of total ridership, the Metro model appears to be accurate.

Two major problems complicate analysis of Metro's use of HOV lanes. First, safety considerations inhibit the use of HOV lanes by Metro buses. A merge to the right into slower traffic is inherently dangerous for a bus driver. A safety guideline requires that Metro drivers begin to merge out of an HOV lane at least 2.5 kilometers before reaching a designated exit ramp. Because most HOV lanes in the Puget Sound area are located along the inside median, the difficulty of merging into an HOV lane and merging out of it soon thereafter reduce the benefit of using the lanes. The net result is that many Metro buses do not use the HOV lanes along their routes. Thus, the travel time savings associated with HOV lane use are precluded by safety concerns. As the HOV lane system is completed, Metro buses will use HOV lanes more frequently because the problem of merging into slower traffic will likely be reduced and travel time savings will increase.

Another problem is that drivers on some routes are instructed to use an HOV lane for either the inbound or the outbound portion of their trips. These problems do not affect

analysis of HOV lane use by Community Transit or Pierce Transit because the routes for both of these transit agencies are so long that HOV lanes provide significant travel time savings while posing fewer safety problems associated with merges into slower traffic.

The data in Table 6.1 show Metro ridership for routes along six of the major freeway corridors containing HOV lanes.

Table 6.1 Average Weekday Ridership for Metro Routes Along HOV Lanes: Metro ridership on routes that use HOV lanes or travel next to such lanes is highest in the spring, lower in fall, and lowest in summer. This trend generally holds true for Community Transit and Pierce Transit routes as well

Route	Fall 97	Spring 98
I-5 South		
@ the Duwamish River	12,700	12,900
I-5 North		
@ the Ship Canal Bridge	18,000	20,300
SR 520		
Across Lake Washington	10,000	11,000
I-90		
Across Lake Washington	7,400	9,200
I-405 South		
Coal Creek Parkway to NE 44th	2,400	2,600
I-405 North		
SR 520 to NE 70th Park & Ride lot	2,800	2,900
Total	**53,300**	**58,900**

Because not all Metro buses use HOV lanes, the figures overestimate true HOV lane ridership. Sifting out the routes that actually use HOV lanes from the ones that do not to generate a true ridership figure would not be financially responsible, because HOV lane use is such a small factor in Metro's route guidelines. One policy option for HOV lane planners is to build special exit ramps for HOV lanes on the inside of the freeway (commonly called "direct access/egress ramps"). One new regional agency, SoundTransit, will provide several of these direct access ramps to various city transit

centers and suburban Park & Ride lots. This option was included during the last public opinion survey period, and the results are presented in Figure 5.19.

Community Transit Ridership

Community Transit supplied this project with ridership data for routes that use HOV lanes. This report includes data for the period between January 1995 and December 1997. Community Transit buses have two destinations in Seattle: the central business district (17 routes) and the University District (eight routes). These routes use the northbound and southbound HOV lanes in the I-5 North corridor and on the express lanes. Figure 6.1 compares 1997 ridership with average ridership from 1995 through 1996 to the central business district (CBD). Figure 6.2 shows the same ridership comparison for Community Transit routes to the University District. Figures 6.1 and 6.2 show the past three years of average total monthly ridership exhibiting the annual growth in Community Transit ridership along these routes. The increase in annual ridership for 1997 to the CBD averaged about 8 percent, but the University District annual ridership remained about the same as 1996 totals. Ridership to the CBD in 1997 increased by more than 250,000 riders from 1996 levels, while ridership to the University District decreased by roughly 8,800 riders for the same period. Monthly ridership in both figures is adjusted to include only weekday, non-holiday service.

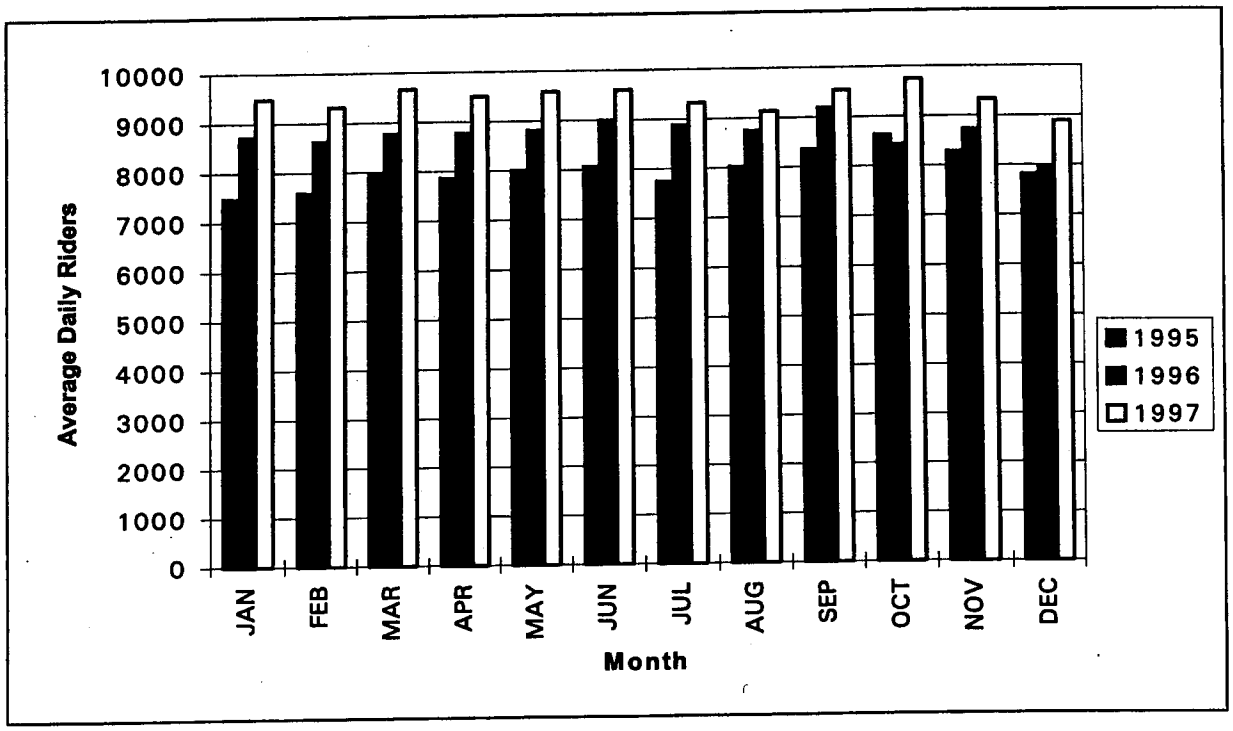

Figure 6.1 Community Transit Average Daily CBD Ridership 1995-1997: (See text below)

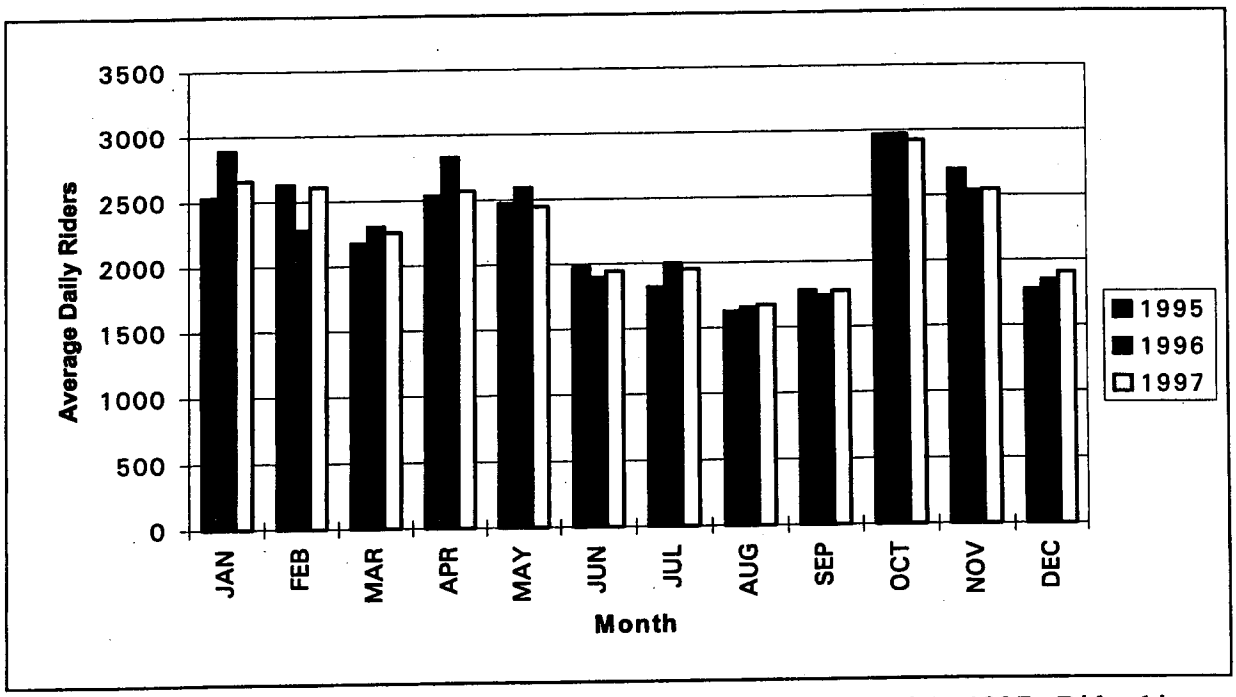

Figure 6.2 Community Transit Average Daily UW Ridership 1995 - 1997: Ridership to the CBD is more stable through the year than to the University District. Downtown employees probably have a more constant need for transit over the year than do students.

Pierce Transit Ridership

Pierce Transit's Seattle Express program operates five transit routes to Seattle. This service started in September 1990. Figure 6.3 shows 1997 Seattle Express total monthly ridership in comparison to average monthly totals for 1995 and 1996. Ridership on Seattle Express buses has grown steadily. 1997 ridership was fourteen percent higher than 1996 ridership. The monthly ridership levels shown in Figure 6.3 include only weekday, non-holiday service.

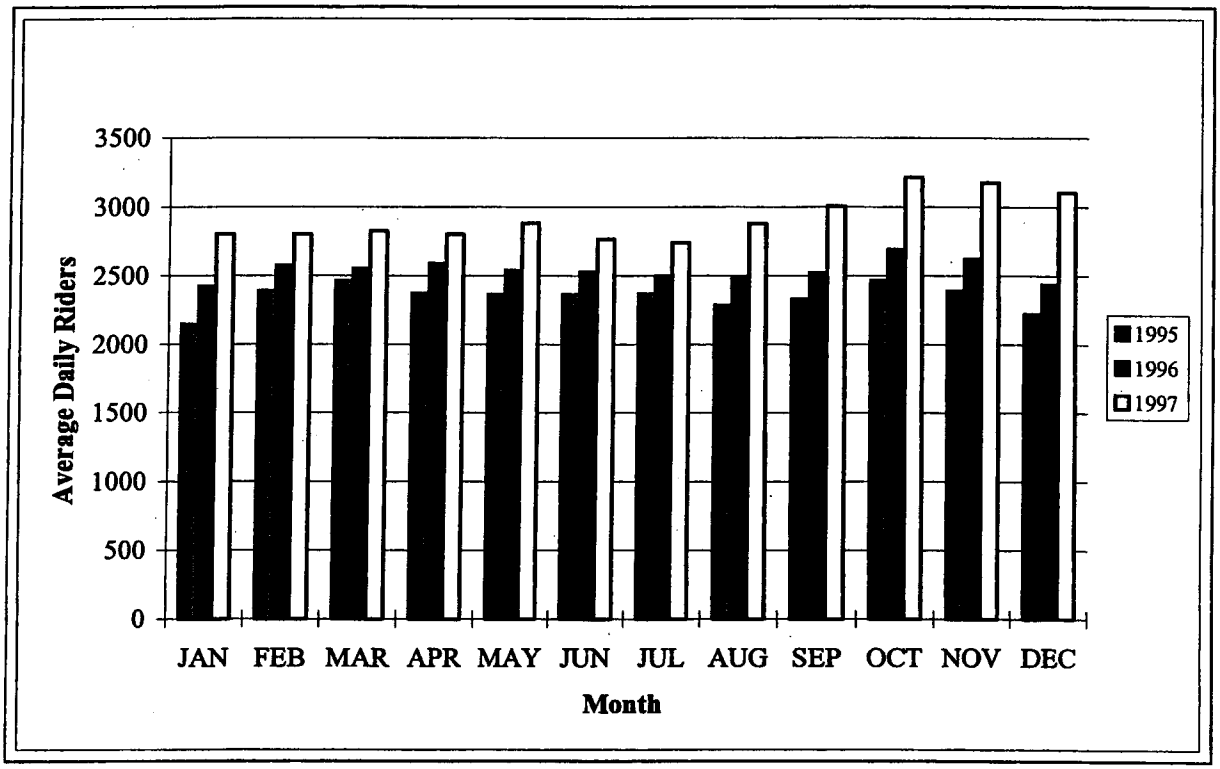

Figure 6.3 Pierce Transit Seattle Express Average Daily Ridership 1995 - 1997: Ridership increased 55 percent since Pierce Transit took over the Seattle Express routes in September of 1994. These routes service a high proportion of the daily riders to Seattle's CBD. Transit ridership peaks in the late fall to early winter.

ENFORCEMENT, COMPLIANCE, AND ADJUDICATION

Two measures of HOV lane effectiveness are (1) the violation rate of HOV lane restrictions, and (2) the outcomes of enforcement actions. We are interested in identifying trends in the number, locations, and outcomes of HOV violations. The occupancy data collected by traffic observers provides some insight into violation rates, but we have collected data from other agencies to supplement this information, such as information from the Washington State Patrol and from the HERO program, which is run by Metro. We gathered data from district courts in counties that have HOV lanes to measure HOV violation outcomes. The Washington State Office of the Administrator of the Courts supplied the data pertaining to the district courts.

In addition to these measures of HOV violations, the public opinion survey devoted four questions to motorists' perceptions of compliance and enforcement of HOV restrictions. Survey respondents ranked improving enforcement as their highest priority for making HOV lanes more attractive (Figure 5.11). About 64 percent of both HOV and SOV drivers agree that HOV violations are common during peak commute hours (Figure 5.26. In addition, about 59 percent of both groups agree that HOV violators commit a serious traffic violation (Figure 5.25). Public response to whether the HERO program helps reduce violation rates were undecidedly neutral. (Figure 5.33)

The HERO Program

The HERO program is a service provided by Metro that encourages motorists to report HOV violators they observe on area highways. The HERO program encourages travelers to call in and report HOV lane violators at the telephone number 764-HERO. The HERO program office collects the license plate numbers of alleged HOV violators and sends that information to the Department of Licensing for the name and address of the vehicle's registered owner. HERO staff then send a brochure to the alleged violator, providing information on HOV lane policy and restrictions. Following a second report,

the violator receives a letter from WSDOT, issued by the HERO office, which explains that the person's auto was observed violating HOV lane restrictions. If a third violation is observed, the vehicle owner receives a letter from the Washington State Patrol (WSP), also issued by the HERO office. The HERO program does not issue tickets because the State Patrol must actually observe the violation. HERO reports repeat violators to the WSP for possible enforcement action. Figure 6.4 shows annual violation report rates for the HERO program.

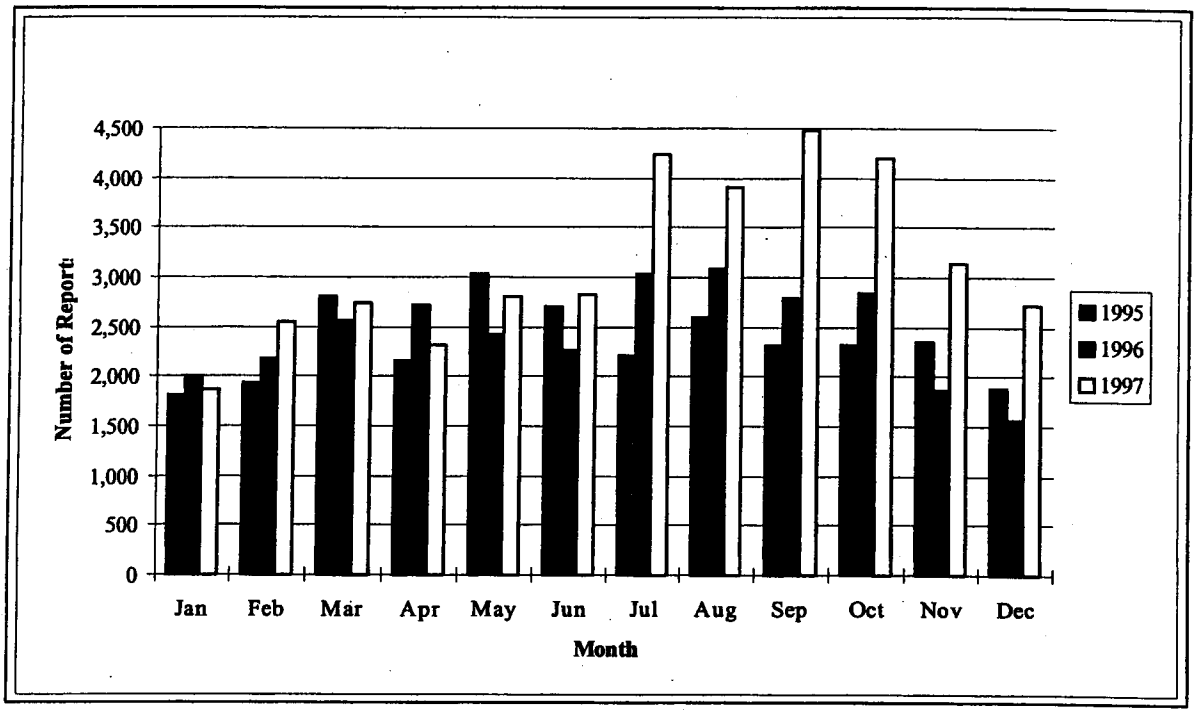

Figure 6.4 HERO Program Actions 1995 - 1997: Violation rates have increased steadily since 1993, with the total annual number of reported violators reaching 37785 in 1997. Reported violation rates decrease in the winter months because of diminished light levels which make it difficult to see the number of occupants or the vehicle license plate of nearby cars.

Washington State Patrol

The Washington State Patrol has primary responsibility for enforcing HOV lane restrictions on state highways. While the WSP catches only a fraction of HOV violators on any single day, repeat violators have a significant chance of eventually getting caught. For 1997 the WSP reported 12,313 contacts with HOV violators and 7,014 issued tickets, for a ticketing rate of over 57 percent. This was the highest ticketing rate in the past six years. Figure 6.6 breaks down those enforcement actions by type.

Table 6.2 Washington State Patrol HOV Enforcement Actions, 1992-1997: The number of tickets issued by officers increased 47 percent over the previous year (1996). Troopers have the discretion to ticket offenders or to give verbal or written warnings as they see fit. WSP has adopted a "zero tolerance" policy regarding HOV violations in an effort to curb persistent violation rates.

Type of Action	Arrest Citations	Verbal Warnings	Written Warnings	Accident Citations	Other	Total
1992	3,790	3,717	248	7	21	7,783
1993	3,655	3,389	259	5	33	7,341
1994	2,809	3,159	225	N/A	11	6,204
1995	3,893	2,734	415	N/A	11	7,053
1996	4,784	5,574	327	N/A	23	10,708
1997	7,014	4,786	503	N/A	24	12,303

Adjudication Data

While reports of violations and the number of warnings and tickets issued provides useful insight into HOV violation rates, it is also useful to know what happens once HOV violators have been ticketed. State troopers refer HOV violators to district courts in the region in which they are ticketed. Those district courts send information on the outcomes of all court cases to the Office of the Administrator of the Courts, in Olympia, for central storage and analysis. That office supplied this project with data on

outcomes for all infractions involving HOV lanes between 1991 and June 1998. The outcomes are as follow:

- Paid. Violator paid fine, no court action required.
- Committed. Violator contested ticket in court and lost, or the violator failed to appear. Failure to appear in court results in an additional fine.
- Not Committed. Court found violator not guilty.
- Dismissed. Court waived charges.
- Dismissed with Prejudice. Infraction dismissed, but court reserved right to enforce the infraction in the future.
- Dismissed without Prejudice. Infraction dismissed, and court waived the right to enforce the infraction in the future.
- Amended. Violator found guilty of a different or lesser charge.
- Pending. Case not concluded as of June 1998.

Figure 6.5 shows the outcomes for HOV violations for 1995 through 1997. Three categories (Dismissed with Prejudice, Dismissed without Prejudice, and Amended) were omitted because there were fewer than five cases in each.

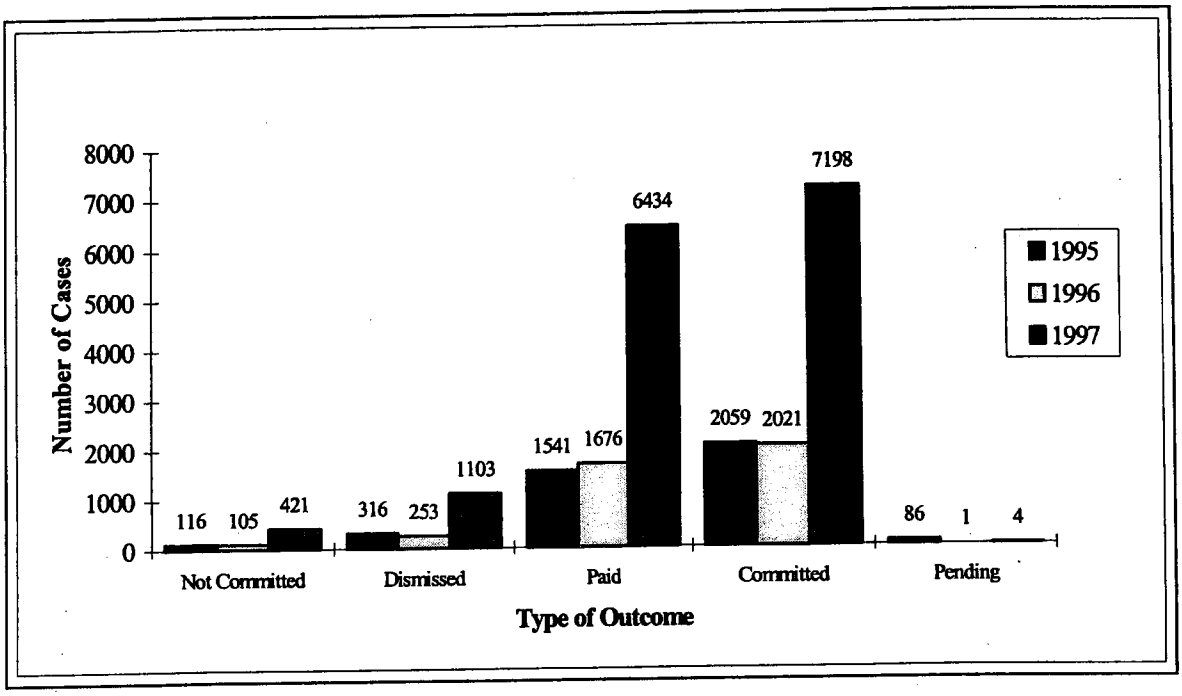

Figure 6.5 HOV Adjudication Outcomes 1995 - 1997: Violations committed in 1997 were up significantly from the 1995 and 1996 results.

The outcome data are also broken down by court district in Table 6.3. The results shown represent the number of cases considered for each classification in each district. Only cases from the eight most active districts are shown; all other cases are grouped under the "Other" category.

Table 6.3 HOV Violation Outcomes by District (1997): Drivers ticketed in most districts tend to pay the fines at roughly the same frequency (37% to 46% of tickets are paid without being contested). The convenience of appearing in court or underlying opinions about the legitimacy of HOV lane restrictions may guide those decisions. Results from the Renton district are higher than the other districts because they represent the combined caseloads of the Renton District Court and the Renton Municipal Court.

District Court	Paid	Committed	Not Committed	Dismissed	Pending	Total
King County: Aukeen	559	563	55	44	0	1221

**Includes Everett, Tukwila, and Sea-Tac District Courts.*

ADJUDICATION DATA RECOMMENDATIONS

1. Conduct a special study of repeat offenders. Data on this subject may be available from district courts. Cross-referencing HERO data with violation outcome data may shed some light on the extent to which violators change their behavior after receiving a ticket.

2. Conduct a special study on highway corridors characterized by chronic violation problems. For instance, according to our ACO data, the HOV lanes on I-405 (just before the I-405/ SR 520 interchange) appear to have a very high violation rate northbound. We believe this is so because the traffic observation point is very close to where HOV lane restriction ends as the highways merge, with an HOV lane merging with two ramp access lanes from SE 8th. This configuration forces traffic from the general purpose lanes to cross the HOV lane. Even though this lane is designated for use by all traffic within the weave zone, as traffic begins to congest, motorists tend to abuse the HOV lane to bypass the congestion. One way to assess the observed violation rate would be to observe traffic at this site and simultaneously at another location 1/4 mile upstream. Follow-up conversations with WSP officials and court clerks and judges may shed light on this trend.

ACCIDENT INFORMATION

WSDOT policy related to the safety of HOV lanes stipulates that HOV lanes should provide safe travel options to HOVs without having a negative impact on the safety of general purpose lanes. HOV lane safety is therefore a key determinant of HOV lane effectiveness. If drivers do not feel safe on HOV lanes, it is likely that fewer drivers

will use those lanes. While the public opinion survey measured *perceptions* of HOV lane safety, an effective evaluation also requires analysis of actual accident rates. Safety impacts of opening HOV lanes and accident trends over time are the most relevant. In addition, a safety comparison among different HOV lane configurations and policies would be useful for planning purposes.

An HOV accident is defined as an accident that occurs following an HOV lane's opening date, between the milepost markers associated with that HOV lane, and in the lane designated as the HOV lane (inside/outside). Also included in this definition are accidents that occur on the shoulder next to the HOV lane. Shoulder accidents are included because a vehicle must be in or pass through the HOV lane to be involved in a shoulder accident. This version of the *HOV Evaluation and Monitoring* report no longer contains actual data or results on accidents occurring along the HOV lanes within the Puget Sound region. This information is presented in a previous report **(WA-RD 393.1)**, dated August 1995, which covered accident data through December 31, 1994. The following section outlines the data collection method used and the analysis process adopted to produce those results.

Data Collection and Analysis

Accident data are supplied by the WSDOT Transportation Data Office. WSP and local law enforcement personnel enter data relevant to each highway accident on a standard form containing information about 90 different factors. These forms are forwarded to WSDOT. Information about 28 of the variables were of interest to this study and are available to users of these data. Beginning in 1988, the Transportation Data Office included a code on the accident data entry form to indicate whether an accident occurred in an HOV lane.

Accident data for each HOV lane were organized to correspond to the traffic observation corridors described earlier. HOV accidents as a proportion of total accidents

for each highway segment were presented; and vital statistics such as the opening date, location, lane miles, HOV lane location, occupancy requirements of each HOV lane, and HOV accidents as a percentage of all accidents were included with each figure. Lane location numbers indicated the position of the HOV lane relative to the right shoulder of the roadway. Higher lane numbers were on the inside, or left shoulder; lower numbers were on the outside, closer to the right shoulder. Any changes in the lane configuration or occupancy requirements were noted with the date of such changes. Where appropriate, data from the public opinion survey were provided to show how specific groups of drivers felt about safety on a particular HOV lane segment relative to the frequency of HOV accidents on that corridor.

Users of these data should be aware that each HOV lane opened at a different time of year. To ensure consistency across different HOV lane segments, accident data for the full first year included in each figure were provided. The accident data presented in the August 1995 report were raw numbers. The data did not represent an accident rate because accident frequencies must be compared to traffic volumes to determine absolute rates. Therefore, while an HOV lane may represent 5 percent of all accidents in a given highway segment, only one-fifth as many vehicles may use that HOV lane as use general purpose lanes. Subsequent users of these data must compare relative lane volumes to derive a valid HOV lane safety evaluation. The accident data for all locations were current through December 31, 1994.

ACCIDENT DATA CONCLUSIONS AND RECOMMENDATIONS

Accident patterns are erratic throughout the region, which makes it hard to generalize about accident trends. However, some summary observations appear valid.

First, HOV lanes located on the outside, or right hand side, of the highway experience more accidents than do HOV lanes located on the inside (see SR 520 and I-405 north and southbound from Sunset to Coal Creek). The problem of merging traffic

entering the highway through the HOV lane onto the general purpose lanes probably accounts for much of this phenomenon. One factor that may account for lower accident levels in HOV lanes on the inside of the highway may be that vehicles that experience accidents while merging across the general purpose lanes on their way to the HOV lane are not counted as HOV accidents. However, valid conclusions about the relative safety of inside or outside HOV lanes depend on traffic volumes. Because traffic volumes are probably greater for HOV lanes on the outside, it is difficult to say that those lanes are less safe than inside HOV lanes.

Second, reducing occupancy requirements does not appear to significantly worsen accident rates for either HOV or general purpose lanes. In only two cases was reducing occupancy requirements associated with an increased number of accidents: I-5 northbound from the Boeing Access Rd. to Swift Avenue, and I-5 southbound from Tukwila to SR 516. However, in other areas, reducing occupancy requirements did not appear to result in significant safety problems.

The following is a recommendation for the continued use of these data.

1. Investigate the accident rates for HOV lanes on the right side of the road in comparison to HOV lanes on the left side of the road to determine which configuration is safer. Safety analysis of each configuration should be factored into future HOV lane planning.

CHAPTER SEVEN: CONCLUSIONS AND RECOMMENDATIONS

This report represents a compilation of the data necessary to evaluate the Puget Sound area's HOV lane system. The data contained herein encompass vehicle occupancy, travel time, public opinion, transit ridership, and violation and adjudication. This report does not include volume information, which is available from inductance loop detectors, and accident information, which was last collected and presented in a previous report (**WA-RD 393.1**) dated August 1995. Inductance loop data are needed to evaluate person throughput and accident rate information; such calculations would complement the data in this report, and together they would allow for a valid evaluation of the HOV lane system.

AVERAGE VEHICLE OCCUPANCY CONCLUSIONS AND RECOMMENDATIONS

Occupancy data were successfully collected from all study sites. Where data are missing, their absence is due to an insufficient number of counts or the fact that no counts were scheduled. This happened for a number of reasons, including inclement weather, poor visibility, having more sites than observers, and dropping some sites from the data collection menu. The impact of having too few successful counts per quarter was that when bad data rendered the counts unusable, data for the entire quarter were possibly lost. During the first two years of the project observations were consistently more numerous for ramp than for mainline locations, and there were more observations for GP lanes than for HOV lanes. This situation was corrected during the fourth quarter of 1994, when more HOV than GP counts were scheduled for mainline locations and more mainline counts were scheduled altogether. Starting the third quarter 1995, the total number of observations was reduced to ten counts per week because of budget cuts that reduced the funds assigned to the project. Fortunately, restoration of funding level during the current

biennium allowed the project to resume AVO and HOVTT observations at the levels called for by the project's creators.

Factors not directly explored in this report include observer performance, and observer and data management. Because observers are unsupervised in the field, they are trusted to begin and end observations on time, and to observe and record vehicle occupancies accurately. Data quality was verified by checking individual files for "gross errors" such as misnamed files and repeated entries (see *HOV Monitoring and Evaluation Tool* (1)). Quality was also validated by comparing current site data with data collected from previous observations at the same location. As the project has progressed, data have become increasingly accurate. With this in mind, the following changes are in order.

Recommendations

1. Continue to prioritize observations at locations that ensure the best use of resources. Safe locations that provide the best visibility over varying conditions, as well as ease of access and scheduling, are obviously preferred. The question of whether counter-flow traffic patterns should be continued at existing locations or expanded at additional locations should be explored.

2. Evaluate the appropriateness of collecting vehicle occupancy data on the I-5 express lanes. Because the express lanes contain both HOV and GP lanes, "before" data for this corridor may be useful in areas where express lane expansion is planned, and they would allow planners to monitor the express lanes' performance.

The occupancy data presented in this report provide valuable information in two areas: (1) the operation and performance of HOV lanes in comparison to GP lanes, and (2) commuter mode choice in the greater Seattle area. Additionally, as the HOV lane

system expands, areas where "before" data have been collected will serve as baseline reference points in assessing the impact of HOV facilities on commuter mode choice. However, a caveat is in order: because loop data are more representative of traffic volumes in these corridors, the data included in this report should be used only to indicate the percentages of mode and vehicle occupancy in the corridors studied.

ACO ANALYSIS CONCLUSIONS

Many factors affect ACO. Therefore, it is important to use a sampling frame that reduces the influence of these factors. However, because it is impossible to perfectly sample all time periods, days of the week, lanes, and ramps at each location for the whole year, it is important to take these factors into account when changes in ACO are analyzed.

After several years of data collection, we have some understanding of these differences. However, if one is conducting such detailed analysis, it is better to apply correction factors (see Chapter 3) than to use the raw data without adjustments.

BASELINE TRAVEL TIME AND HOVTT (FCM) DATA CONCLUSIONS AND RECOMMENDATIONS

The usefulness of the baseline (license plate matching method) travel time data presented in this report is limited. Although the data can generally be used to compare HOV lane performance to GP lane performance and to identify areas of congestion, a number of factors render data interpretation difficult. Vehicle speeds can only be compared by time of commute for the quarter in which they occurred. Because the data are presented as average speeds, only individual study sections may be used; the data cannot be aggregated to examine the differences between HOV and GP lanes corridor-wide. Because the speeds indicated for areas tend to vary widely from quarter to quarter, yearly averages are unreliable. To determine the number of observations required for

statistically meaningful information, the standard deviation for each time period must be established. Additional data will be necessary before reliable generalizations regarding vehicle speeds can be made.

It was much more difficult and complex to collect baseline travel time data than it was to collect vehicle occupancy or travel time data using the floating car method. Observers not only had to be more accurate and have better visibility, they also had to coordinate their efforts more carefully. Even with good data, matches were difficult to obtain because of normal traffic behavior (e.g., lane changes), especially over long distances. Despite the obstacles that made it difficult to collect the baseline travel time data, the experience gained in this study indicates that travel time data may be collected successfully under some conditions. The greatest volume of baseline travel time data was gathered at study sections characterized by good visibility, short length, and high numbers of observations.

Recommendations

1. Use short study sections. Distances between sites should be kept to under three kilometers and should be chosen to limit the number of intervening access/egress ramps.

2. Conduct observations using the express lanes. Not only do the express lanes have GP and HOV designations, they also constitute a "captive audience" in that vehicles may not exit for longer distances. As a result, it may be easier to obtain the necessary matches.

3. Data collection along the I-405 corridor should cover shorter distances and use fewer locations. For example, efforts might be more successful if observations were limited to two study sections (Tukwila Parkway and Benson Road S; 112th

Avenue SE and NE 12th Street) for morning northbound and evening southbound commutes.

Effective collection of baseline travel time data requires a great deal of coordination between observers to ensure that they begin and end at the same time, as well as corridor sections that facilitate license plate matches. Even when travel time data are effectively collected, they can vary so much that routinely gathering data to establish an "overall" travel time statistic for a length of corridor may not be very useful. Because of this fact, future travel time data will be collected by means of the floating car method discussed in Chapter 4. The following recommendation is proposed to better facilitate the collection of HOVTT (fcm) travel times.

4. Index funding for data collection efforts with the addition of HOV lanes miles. Maintaining current HOVTT (fcm) and ACO data collection for all sites originally observed during the baseline data collection period is required to evaluate the effect HOV lanes have on regional traffic patterns. Additional support will be required from associated agencies to obtain significant samples of data for HOV lane evaluations.

It is important to maintain levels of data collection so that time-based trends are not missed because of insufficient data. To maximize the project's resources, HOVTT (fcm) travel time data will be collected during the first and fourth quarters of each year, when limited light conditions make ACO data collection less reliable.

PUBLIC OPINION SURVEY CONCLUSIONS

There is strong public support for HOV lanes in general and for future HOV lane construction. Although there are differences of opinion on many issues between SOV drivers and those who rideshare, these differences do not undermine general support for HOV lanes among the entire survey population.

One sentiment evident throughout the survey was that while the public supports HOV lanes, many people feel that the lanes are not being fully utilized. The results from questions presented in Figure 5.12 through 5.32 should assist planners in selecting the HOV lane policies that will make the lanes more attractive to the public. Results from these survey questions will be valuable in assessing the desirability of these policy options.

Recommendations

1. Conduct periodic reviews of the survey to ensure the appropriateness of its content. Interest in various issues related to the HOV lanes change frequently. Therefore, the survey needs revisions periodically so that planners have data on public sentiment towards new HOV lane issues.

ENFORCEMENT DATA CONCLUSIONS AND RECOMMENDATIONS

The ACO data, violation data from WSP, HERO program data, and adjudication data from the district courts provide a comprehensive picture of the extent of HOV violations in the Puget Sound area. Violation rates would be the most appropriate measure for evaluation purposes because they combine the number of cars using an HOV lane with the frequency of violations. Identification of the HOV lanes with the highest violation rates would provide valuable information to WSP troopers for their enforcement efforts. The ACO data presented in Appendix B provide an indication of violation rates (the number of SOVs observed in HOV lanes). Both WSP troopers and district court

judges exercise a great deal of discretion in enforcing HOV lane violations. If WSDOT or other public officials desire to increase enforcement of HOV lane restrictions, consultation with these groups is in order.

Recommendations

1. Conduct a special study of repeat offenders. Data on this subject may be available from district courts. Cross-referencing HERO data with violation outcome data may shed some light on the extent to which violators change their behavior after receiving a ticket.

2. Conduct a special study on highway corridors characterized by chronic violation problems. For instance, according to our ACO data, the HOV lanes on I-405 (where SR 167 merges with I-405) appear to have a very high violation rate. We believe that this is so because the traffic observation point is very close to where the highways merge, with a general purpose lane merging into an HOV lane on I-405. One way to assess the violation rate would be to observe traffic at that spot and at another spot one-quarter mile downstream simultaneously. Follow-up conversations with WSP officials and court clerks and judges may shed light on this trend.

ACCIDENT DATA CONCLUSIONS AND RECOMMENDATIONS

Accident patterns are erratic throughout the region, which makes it hard to generalize about accident trends. However, some summary observations appear valid.

First, HOV lanes located on the outside, or right hand side, of the highway experience more accidents than do HOV lanes located on the inside (see SR 520 and I-405 north and southbound from Sunset to Coal Creek). The problem of merging traffic

entering the highway through the HOV lane onto the general purpose lanes probably accounts for much of this phenomenon. One factor that may account for lower accident levels in HOV lanes on the inside of the highway is that vehicles that experience accidents while merging across the general purpose lanes on their way to the HOV lane are not considered HOV accidents. However, valid conclusions about the relative safety of inside or outside depend on traffic volumes. Because traffic volumes are probably greater for outside HOV lanes, it is difficult to say that those lanes are less safe than inside HOV lanes.

Second, reducing occupancy requirements does not appear to significantly worsen accident rates for either HOV or general purpose lanes. In two cases, reducing occupancy requirements was associated with an increased number of accidents: I-5 northbound from the Boeing Access Rd. to Swift Avenue, and I-5 southbound from Tukwila to SR 516. However, in other areas, reducing occupancy requirements did not appear to cause significant safety problems.

Recommendation

1. Investigate the accident rates for HOV lanes on the right side of the road in comparison to HOV lanes on the left side of the road to determine which configuration is safer. Safety analysis of each configuration should be factored into HOV lane planning.

ACKNOWLEDGMENTS

The authors gratefully acknowledge the following agencies for the information they provided:

- Metro, for transit ridership and HERO data
- Community Transit, for transit ridership data
- Pierce Transit, for transit ridership data
- the Washington State Administrator of the Courts, for adjudication data
- the Washington State Department of Transportation, Traffic Data Office, for accident data
- the Washington State Patrol, for violation and accident data.

The authors also express their appreciation to TRAC staff, including Duane Wright, Ron Porter, Amy O'Brien, and Stephanie MacLachlan for their assistance in formatting the numerous tables and diagrams, as well as editing the body of this report. Eldon L. Jacobson, WSDOT--Advanced Technology Branch; Barbara Miller and Patrick Purvus, former Observations Managers; Graciela Etchart, Matthew Hansen, and Matthew Benuska, the authors of the original report (1); and the late Cy Ulberg, the principal investigator, were valuable resources. Finally, this report is dedicated to the traffic observers. Through many hours spent counting cars in all kinds of weather, they provided much of the data, without which this report would not have been possible.

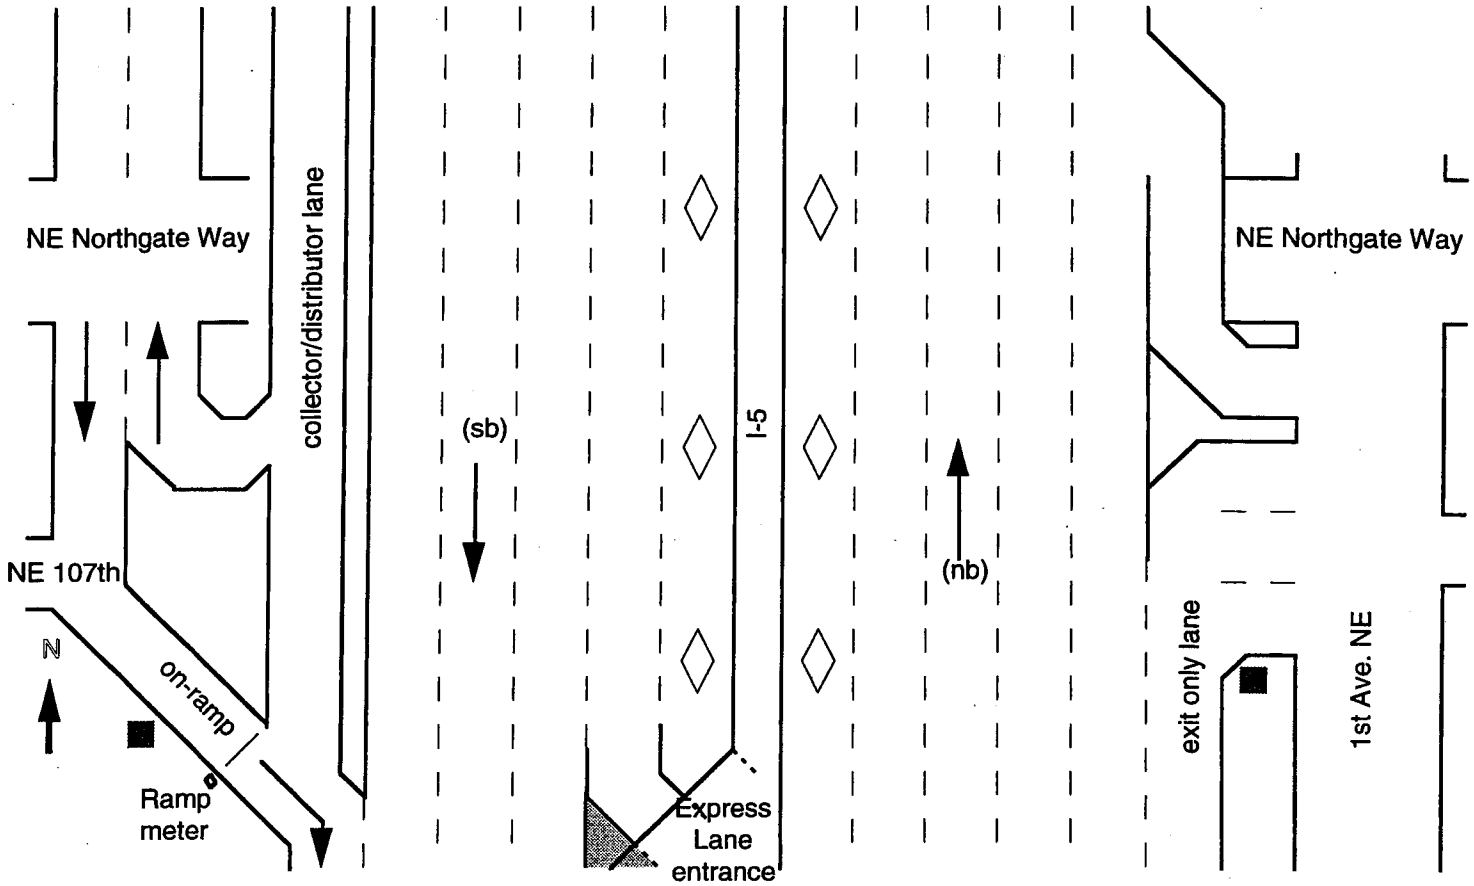
SITE #16. I-5 NORTH - NE Northgate Way

- **ACO on/ramp SB-am**
- **ACO off/ramp NB-pm**



Note: Counting the southbound on/ramp traffic means you have to count all the cars on the collector/distributor lane. To do this, walk down the ramp until the c/d lane merges into one, and sit behind the jersey barrier for safety.

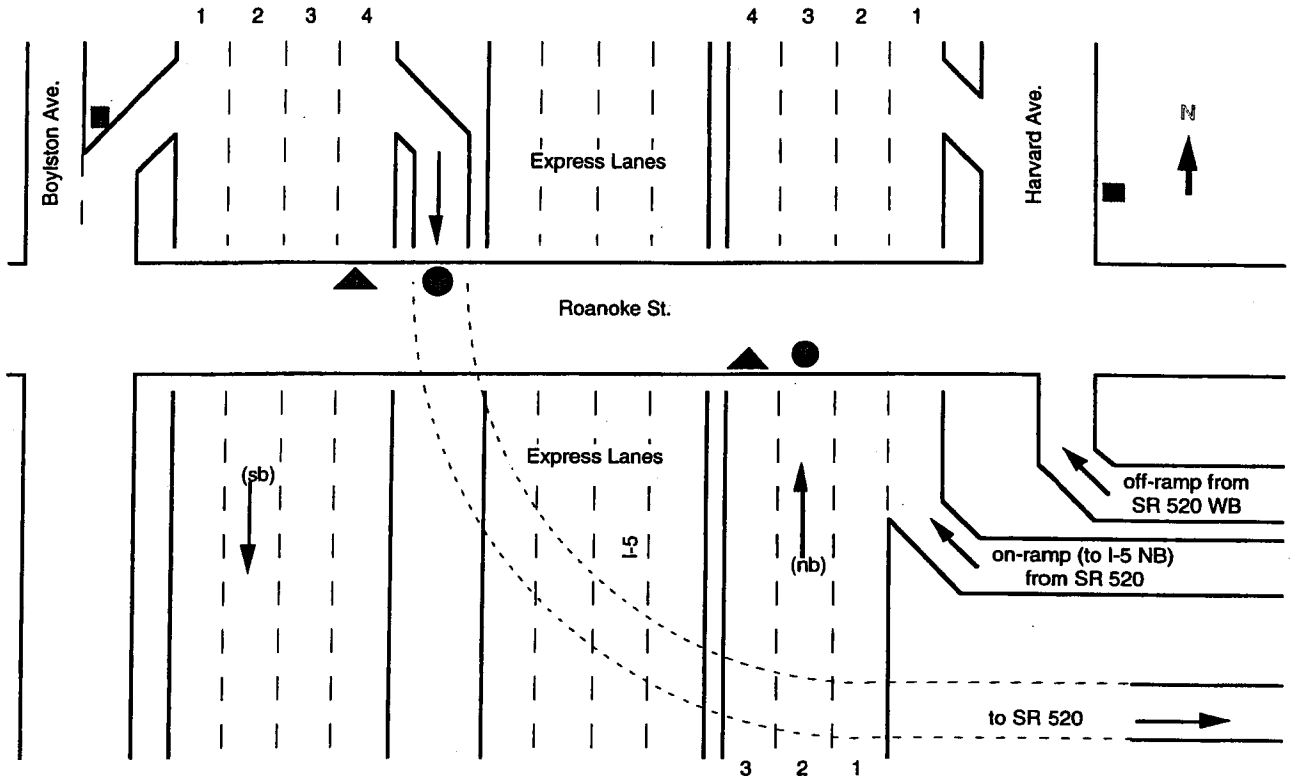
SITE #21b. I-5 DOWNTOWN - Roanoke Boulevard

▲ **ACO mainline SB & NB-am & pm**
■ **ACO off/ramp SB-am & pm**
■ **ACO on/ramp NB-am & pm**



Directions: Take I-5 south from 45th Avenue NE, and take the first exit south of the ship canal. To count either mainline or southbound off/ramp traffic, find a place to park along the side of the street (you may need to turn right on Roanoke and go around the block).

To count northbound on/ramp traffic, turn left on Roanoke, cross over the mainline, and turn left again on Harvard Ave. The on/ramp is about a block down on your left. You can park across the street in the residential area, and sit on the sidewalk just to the south of the ramp.

Note: Do not count the express lanes at all in this location. The off/ramp southbound merges with traffic on Boylston Avenue East. You have to sit someplace where you can see clearly only the ramp traffic.

I-5 Downtown - Roanoke Blvd.

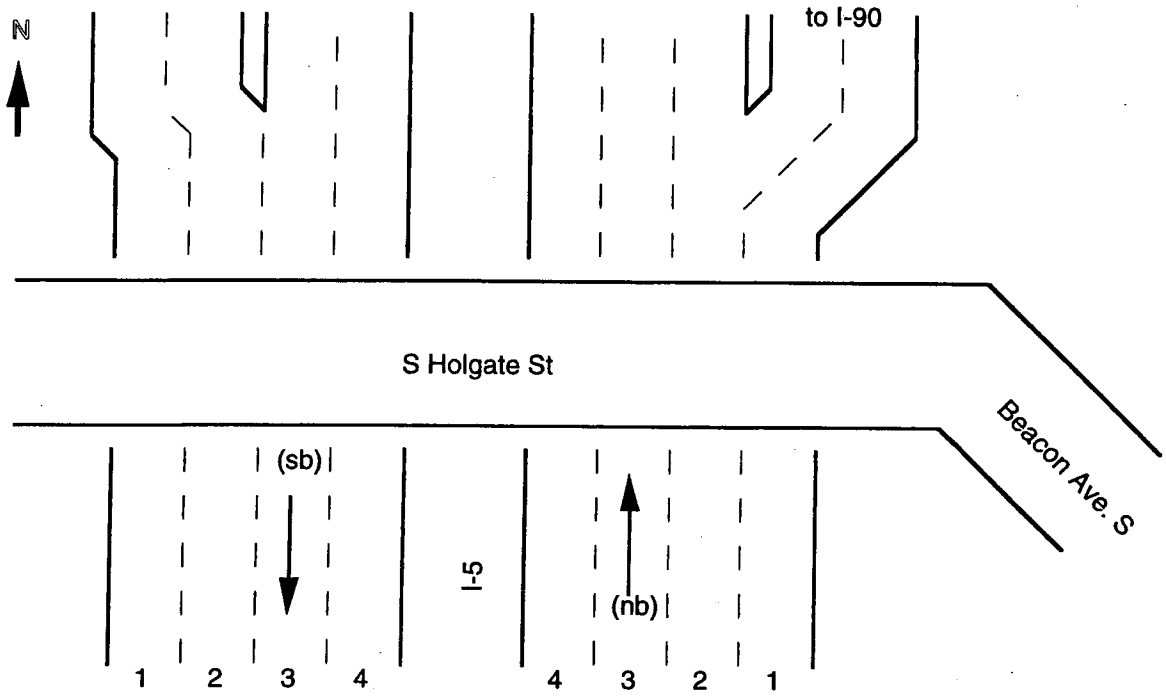
SITE #22. I-5 DOWNTOWN - S. Holgate Street

ACO Mainline SB & NB-am & pm



Note: There is a sidewalk only on the north side of Holgate over the freeway, so counting northbound travel times must be done with traffic moving away from you. The southbound lanes are on a considerably lower level than the northbound lanes, and are consequently somewhat harder to see.

Observations at site discontinued Q4/92.

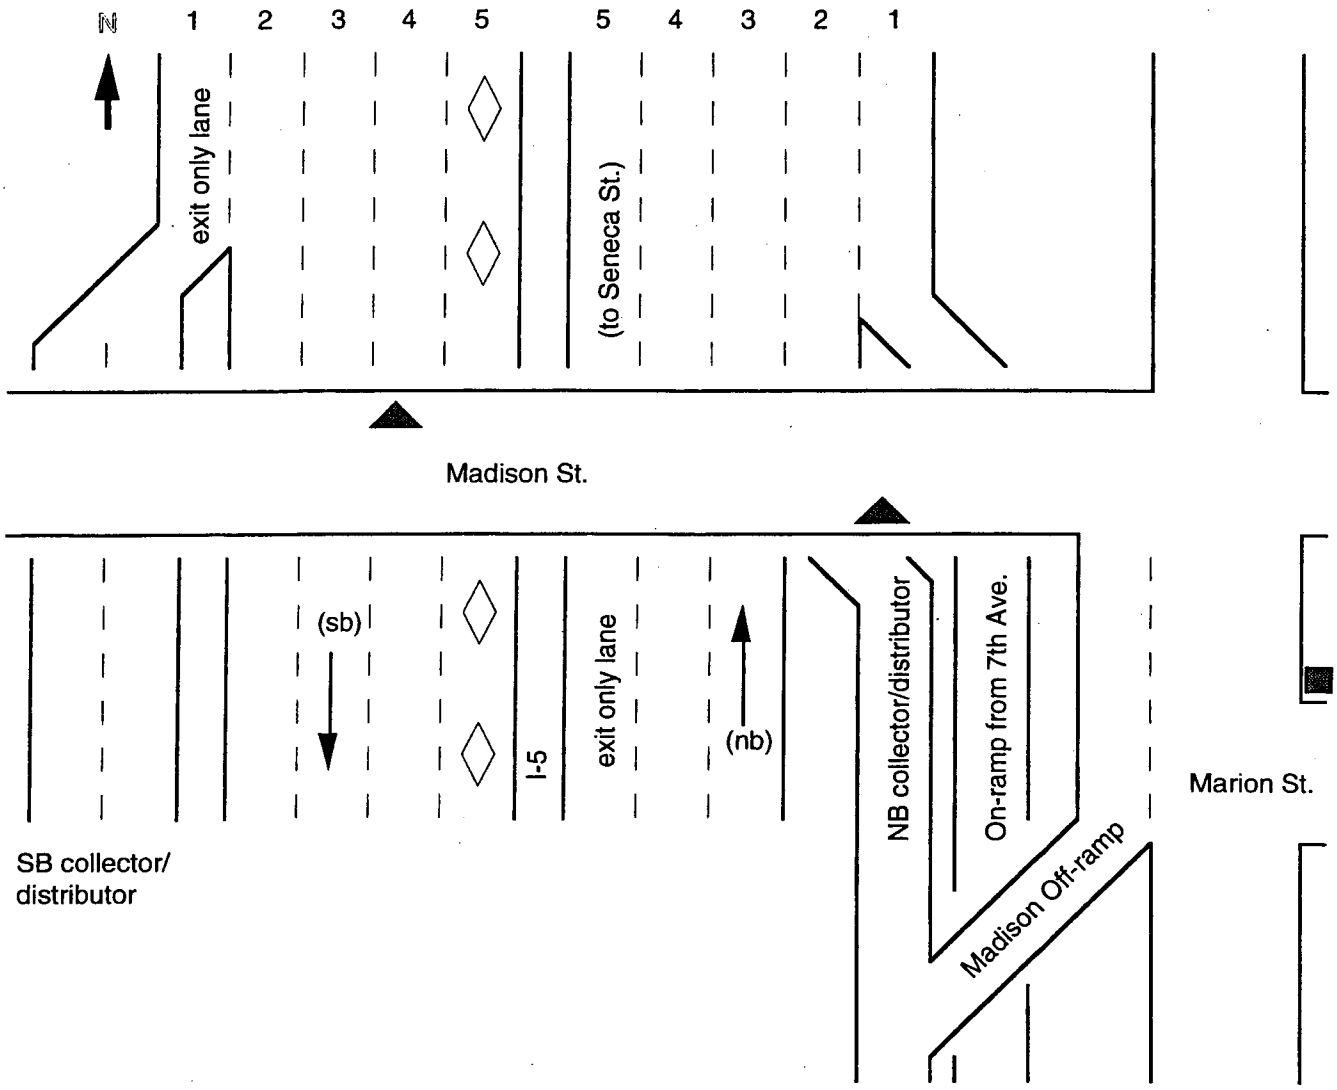
SITE #29. I-5 DOWNTOWN - Madison Street

ACO mainline SB-am & pm
ACO off/ramp NB-am



Note: The southbound mainline site was observed by special request to evaluate HOV lane effectiveness. SB HOV lane went from 3+ persons to 2+ persons 8/18/93.

Count the collector/distributor lanes at this location as lanes #1 and #2 in each direction (this is different than most other sites with collector/distributor lanes). When counting the off/ramp northbound, be sure to include only the traffic coming off the freeway, and not traffic merging from 7th Avenue.

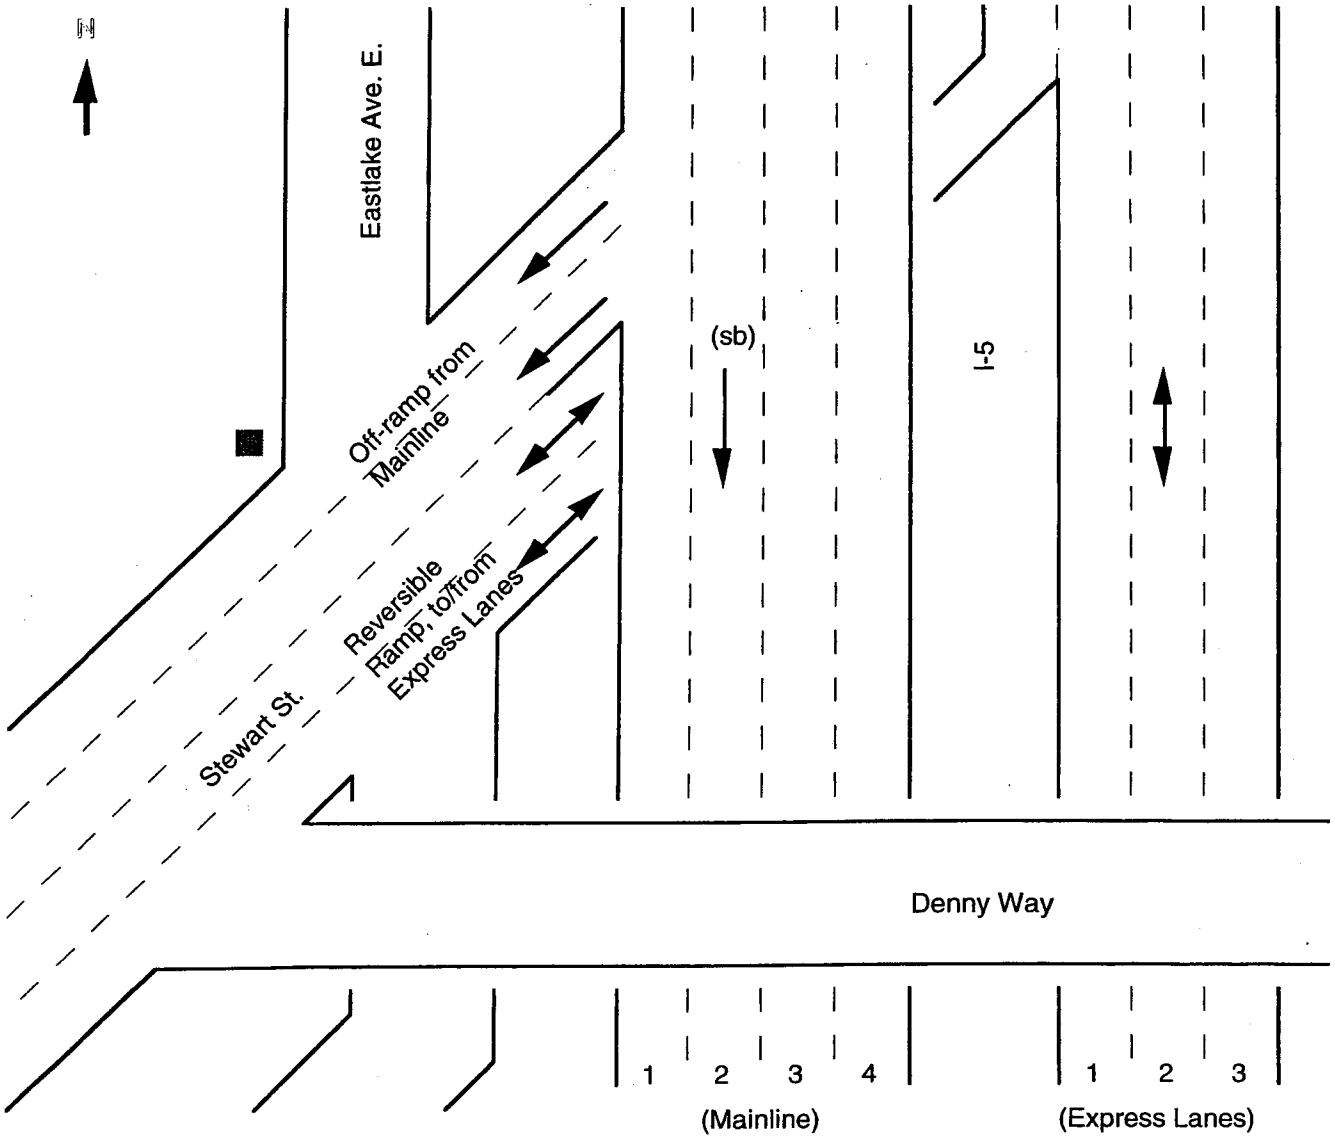
SITE #20. I-5 DOWNTOWN - Stewart Street

ACO off/ramp SB-am & pm



Note: The best place to sit is on the triangular island directly across the street from the ramp traffic as it goes through the stoplight at Eastlake Avenue. The two lanes to the north at the stoplight are traffic from the mainline, and the two lanes to the south at the stoplight are traffic from the express lanes. **Do not count the express lane off/ramp traffic.** Count both mainline off/ramp lanes at the same time.

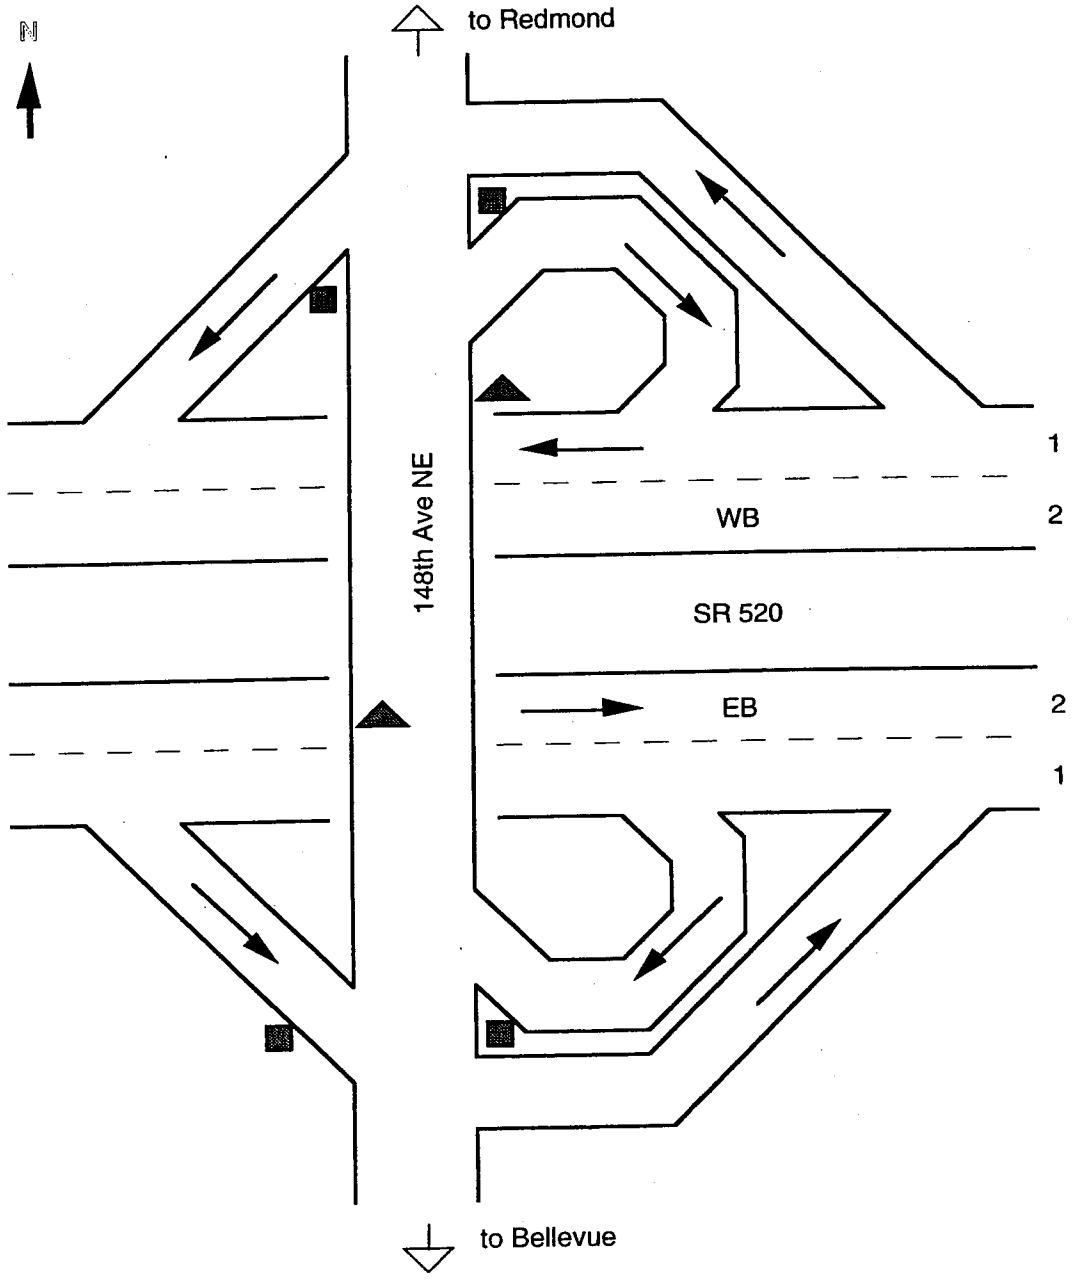
Note: This is a very busy ramp, so it is a good idea to have a vest with you for visibility and safety.

SITES #45, 46, & 47. SR 520 - 148th Avenue NE

▲ **ACO mainline WB-am & EB-pm**
■ **ACO on/ramp WB from Bellevue-am & from Redmond-am**
■ **ACO off/ramp EB to Bellevue-pm & to Redmond-pm**



Note: To count ACO mainline westbound in the morning, you must walk down the east side of 148th NE and go behind the concrete overpass barrier to find a place to sit in the grassy embankment. You will be looking down and to the side to see the mainline traffic.

To count ACO mainline eastbound in the afternoon, you can sit on the sidewalk on the west side of the 148th NE overpass. The entrance and exit ramps in this location are split, so you have to look carefully to be sure you are counting the correct ramp.

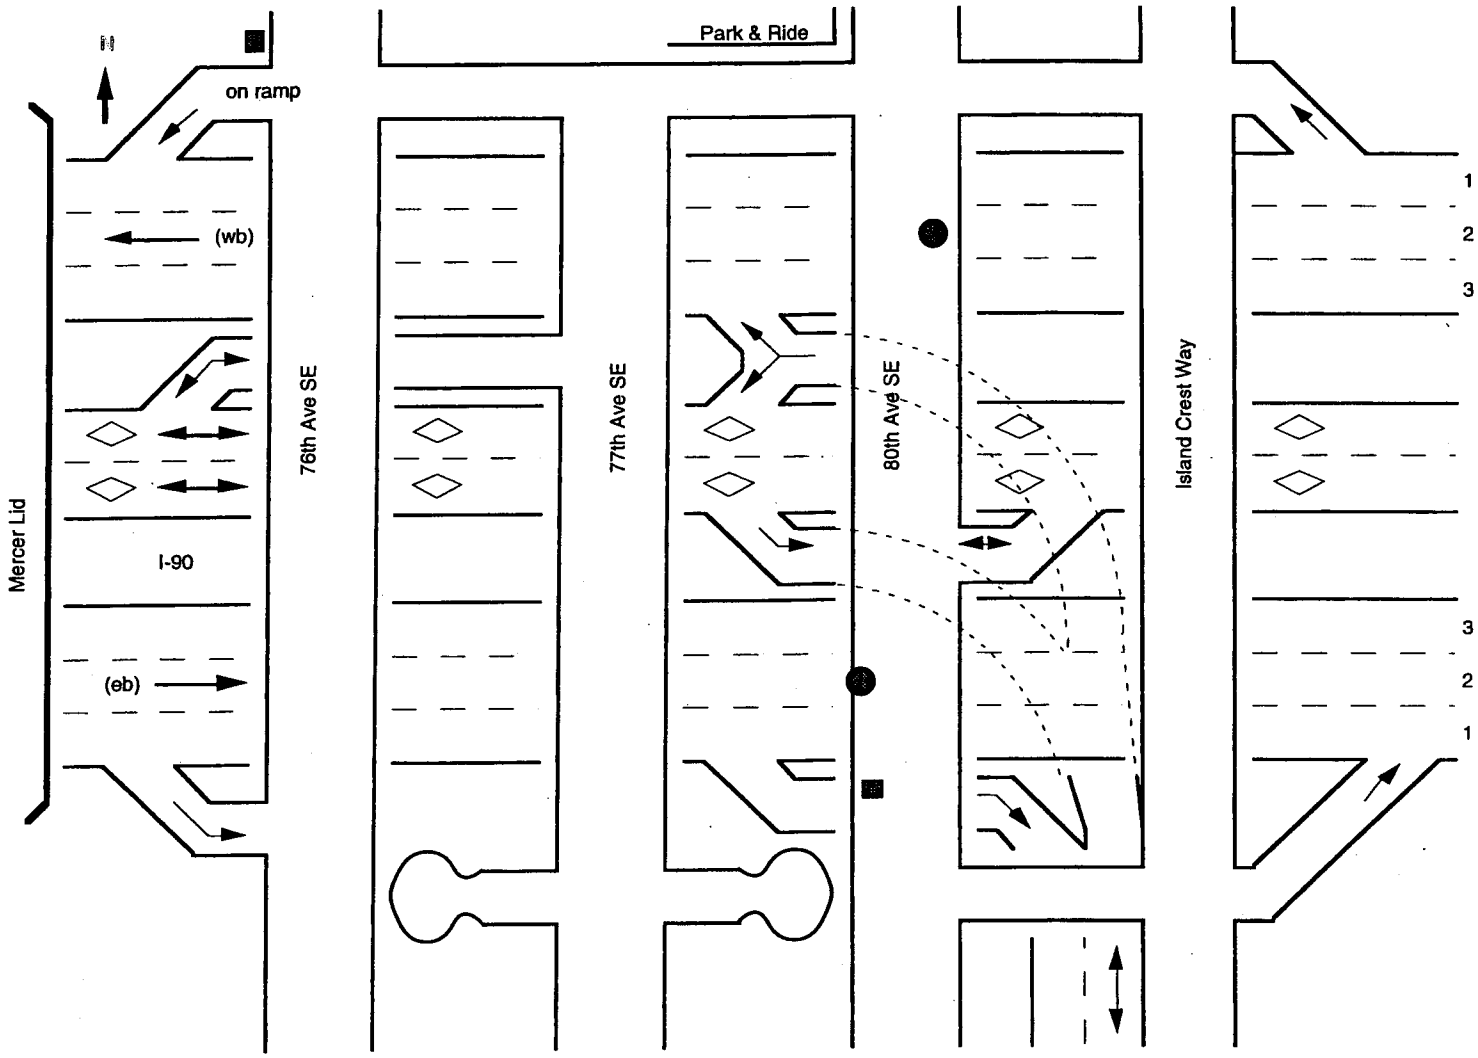
Site # 54. I-90 - Island Crest Way

Beginning Q2/94: **See preceeding pages for data prior to HOV lane completion.**



Note: The on/ramp westbound at this location is actually located at 76th Avenue SE. Occasionally the sprinklers in the landscaping will turn on unexpectedly, so it is a good idea to always have plastic bags and ponchos with you when you count at this location! HOV lanes are counted at Site #52.

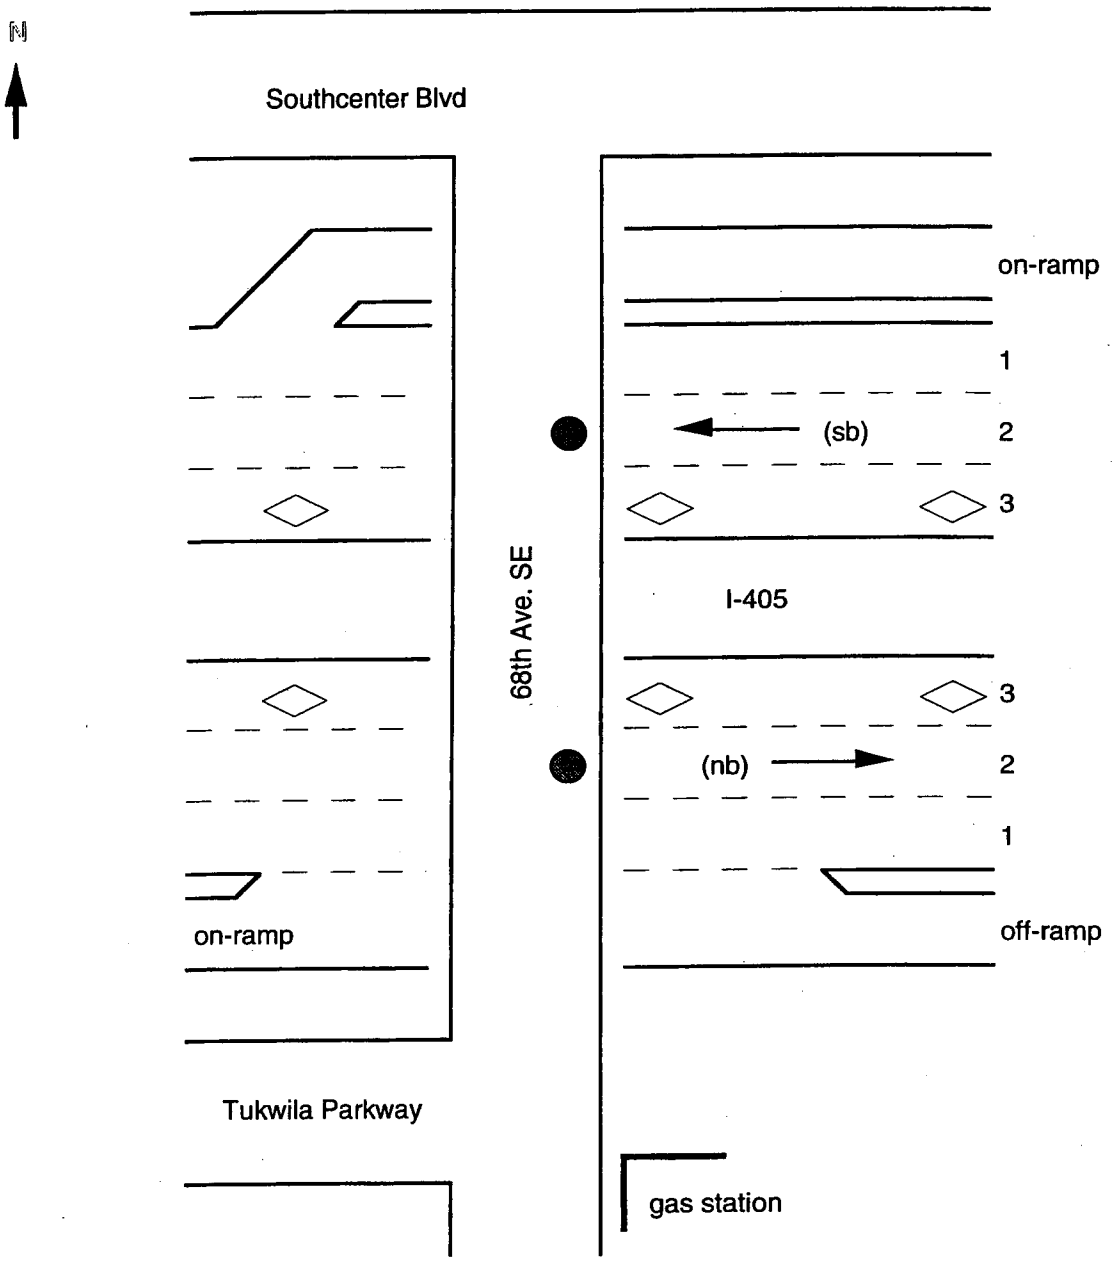
SITE #61. I-405 SOUTH - Tukwila Parkway

▲ **ACO mainline NB & SB-am & pm**



Note: The freeway here is called I-405 North and South, but you will actually be looking east or west when you observe traffic. Northbound I-405 goes east toward Bellevue, and southbound I-405 goes west toward the airport. Be sure to indicate north or south in the program.

There is a sidewalk on only the east side of Tukwila Parkway. In order to count northbound I-405 traffic on the mainline at this location, you have to cross the street, step over the jersey barrier, and sit on the very narrow strip of dirt at the very edge of the overpass. You will be looking down and to the side at the mainline traffic. Be sure to wear a vest in this location.

I-405 South - Tukwila Parkway

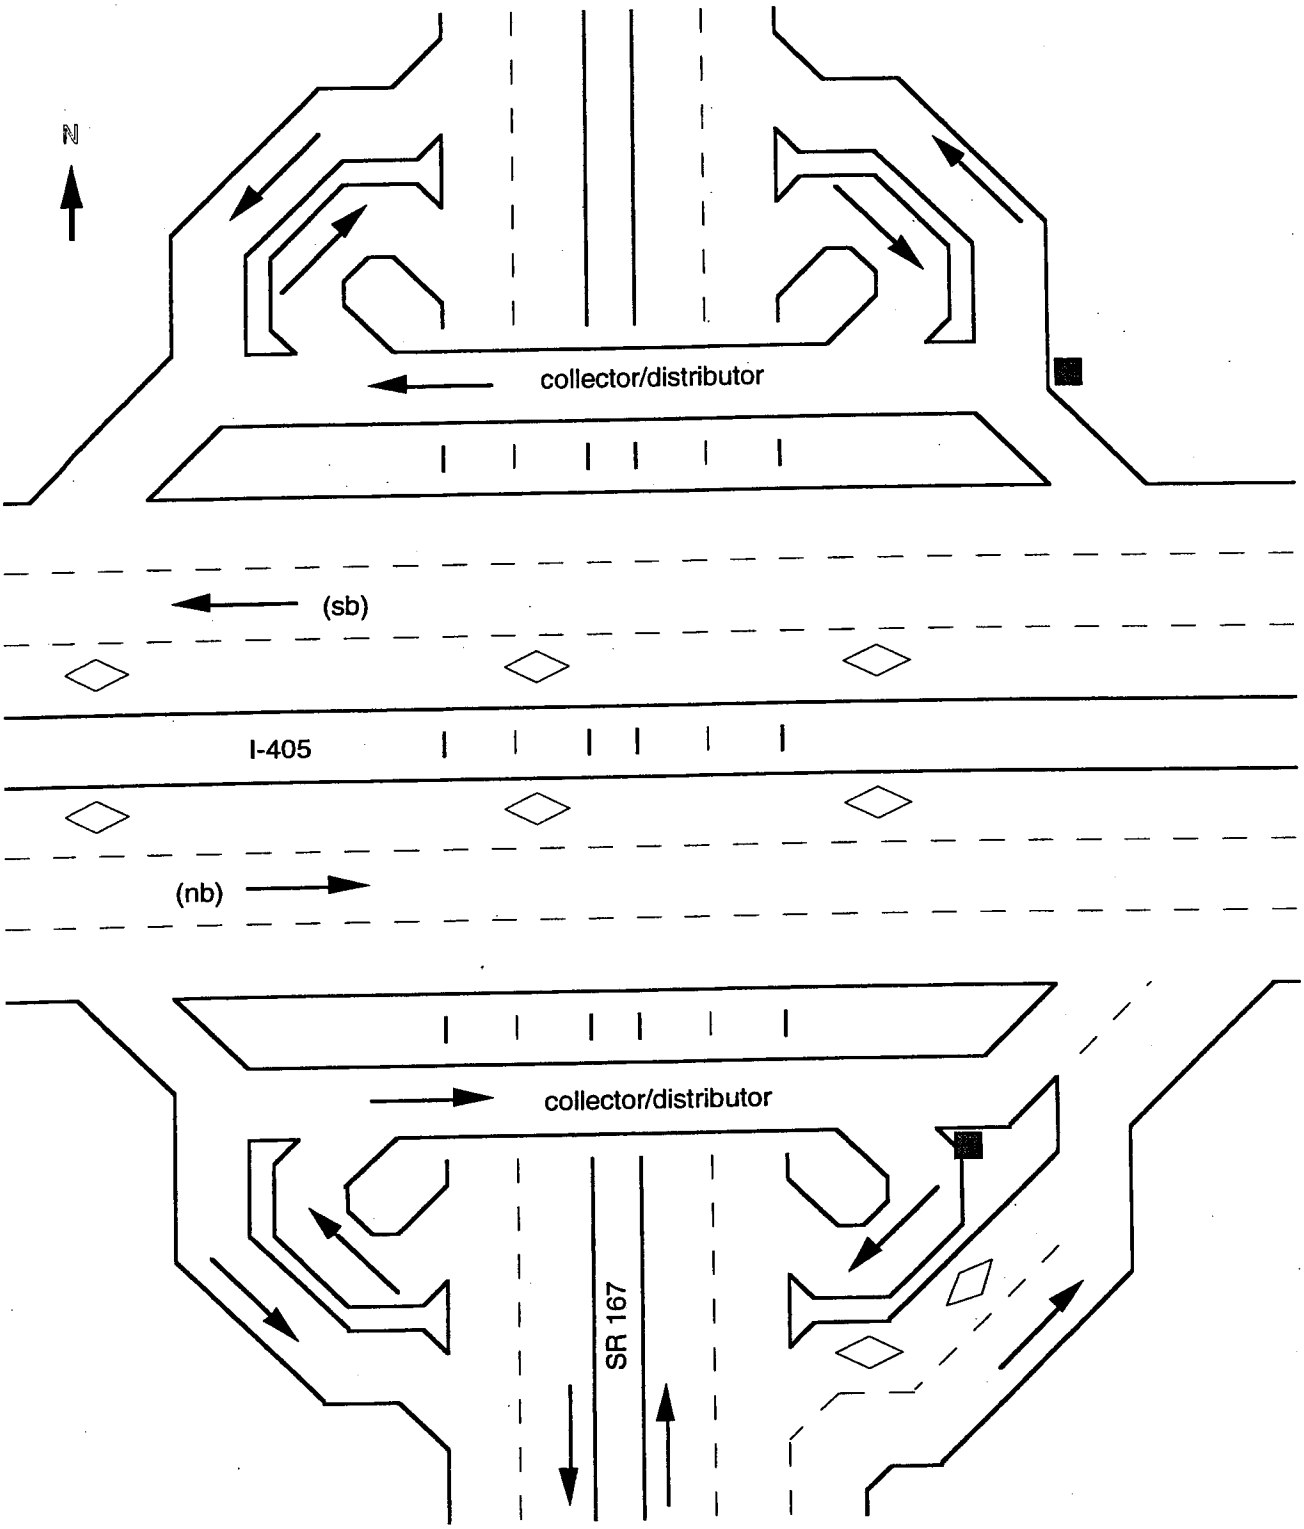
SITE #62. I-405 SOUTH - SR 167/Rainier Avenue South

■ ACO on/ramp NB-am & pm
■ ACO off/ramp SB-am & pm



Note: The on/ramp northbound from SR 167 to I-405 is very busy, and traffic travels at near-freeway speeds most of the time. The off/ramp southbound is just as busy, but traffic may not be traveling quite as fast. It is very important that you wear a vest in each of these locations, and stay protected as much as possible from oncoming traffic.

Since these are split ramps in all directions, you will need to determine in advance and be quite clear about exactly which ramp in which direction you are to observe.

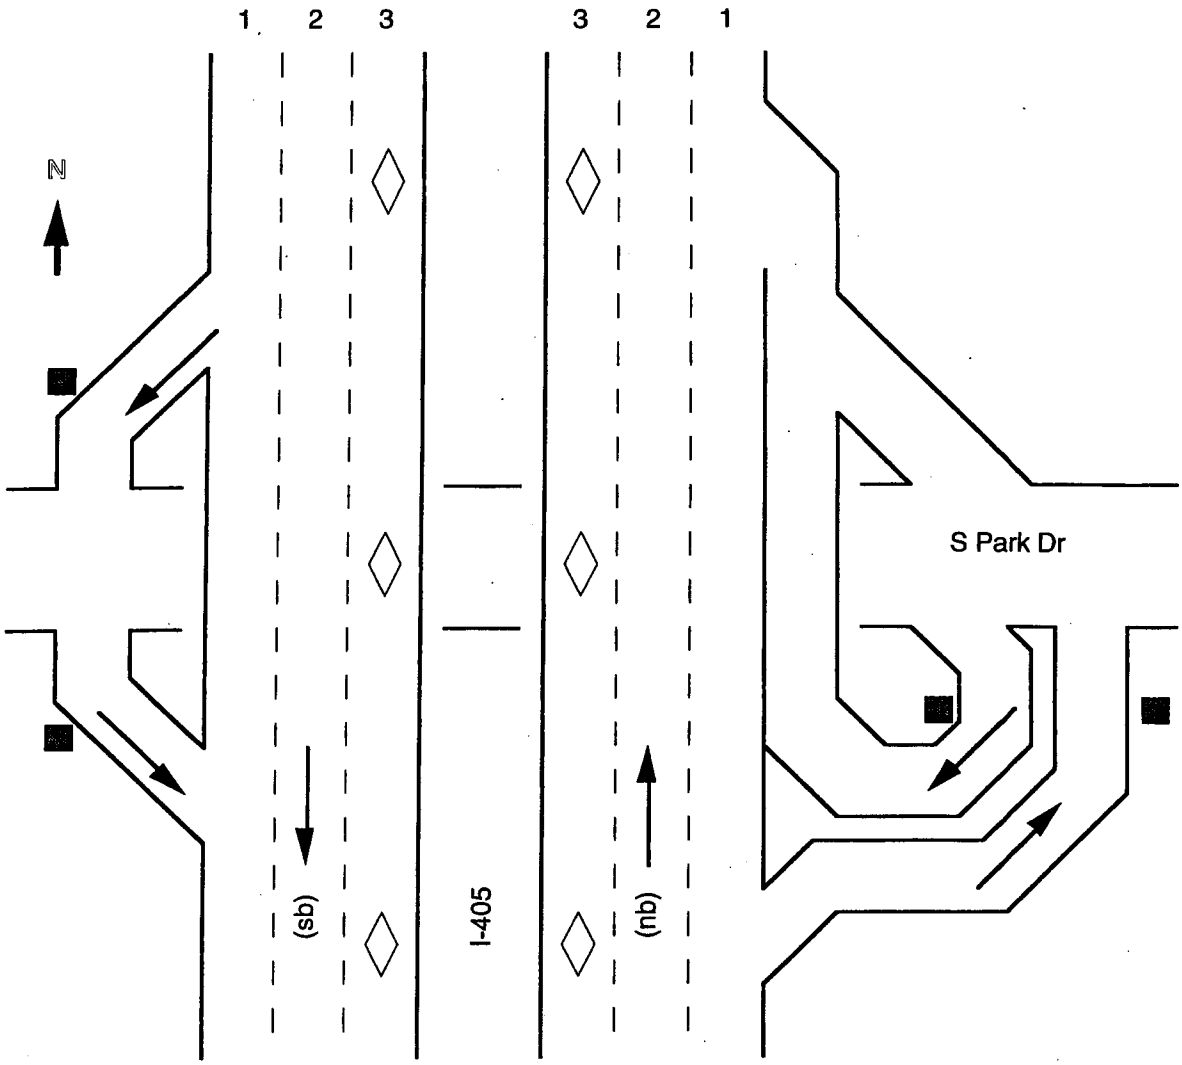
SITE #64. I-405 SOUTH - S Park Drive

■ ACO on/ramp NB & SB-am & pm
■ ACO off/ramp NB & SB- am & pm



Note: There are a lot of Boeing plants and offices in this part of Renton, so traffic conforms to Boeing work schedules. If possible, it is a good idea to count these ramps from 5:30-8:30 in the morning, and from 2:00-5:00 or 5:30 in the afternoon. You will notice a significant drop in traffic after the shift change commute ends. HOV lanes switched from outside to inside Q1/97.

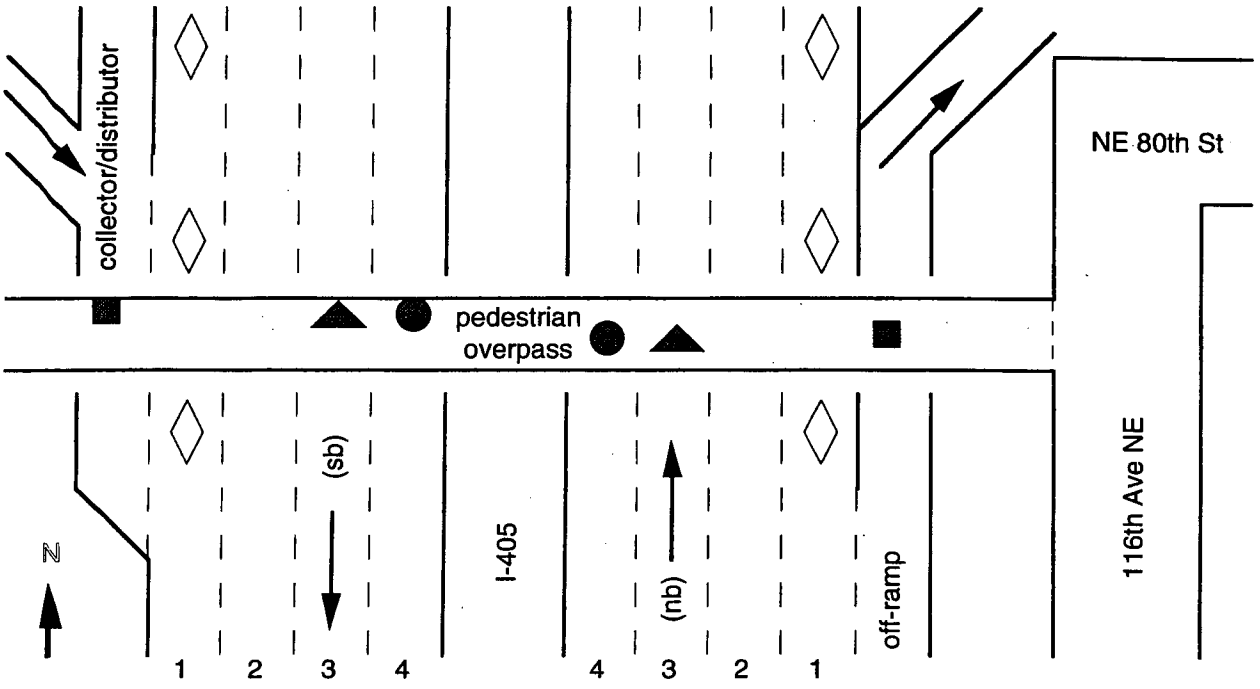
I-405 North - SR 908: Central Way/NE 85th

Beginning Q4/94: See preceding pages for data prior to HOV lane completion.



Note: In the winter, you can also park on the shoulder of each ramp in order to gain better visibility for ACO ramp counts.
The northbound HOV lane opened to traffic on December 18, 1994.
The southbound HOV lane is scheduled to open late summer/early fall, 1995.

* ACO low due to high percentage of violators in most counts.

APPENDIX C

Observer Comments Made During Vehicle Occupancy Sessions

Below is a sample of comments made by observers while collecting occupancy data throughout this period. Generally, these comments can be categorized into three types: comments regarding data collection, comments about traffic conditions, and comments about weather conditions. Ellipses represent time gaps between comments made by the observer. Because the length of comments is limited by the program used, words are sometimes cut off.

DATA COLLECTION

1. actually counting i-5nb off/r at madison st. mainline's moving well.

2. hard to see people in the back seat due to the angle

3. cars in this lane enter a patch of shade just before i can see them clearly, and don't emerge until just before they go under the overpass. on such a bright, sunny day, it makes it hard to see into back seats, esp in dark colored cars.

4. rolling slowdown, site is ok, sidewalk on s side is too narrow, so I'm watching them going away from me

6. just lost a file I started at half capacity battery I couldn't believe it

7. just lose a count, battery dead backup battery is also not full?! I will count as much as it can do

8. hve to go to meet other observers

9. no light for the inside lanes.....end counting

10. trying to get bus numbers

11. taking a break

TRAFFIC CONDITIONS

1. traffic in fast lane came to an abrupt stop one car skidded- almost a crash.....traffic is flowing smoothly again, but traffic speed is less than 55.....another quick stop in the fast lane along with some more burnt rubber.

2. CARS ENTERING FROM TOWN CROSS OVER LANES HER

3. MAINLINE OFF-RAMP AT STEWART ST. ST.....EXPRESS LANE OFF-RAMP CLD BE COUNTED HERE BY A SECOND

PERSON.....THERE ARE POSSIBLY, AGAIN AS MANY CARS EXITTING FROM THE EXPRESS LANES AS THIS

4. TRAFFIC HAS MOVED WELL ALL MORNING, ONLY ONE SLOW-DOWN

5. JUST AS THIS LANE COUNT CLOSES, THE SPEED OF FLOW DROPS TO A CRAWL

6. THE BUSES HAD NO PASSENGERS

7. congestion because of traffic lights occurred during the last 20 minute

8. mainline is moving very slowly. The motorcycle that exited here had 2 occupants

9. foggy-49 degrees, wet road.....traffic is heavy but is moving.....traffic slows down.....stop and go traffic.....my battery is running out.....accident below the overpass.....I think the driver saw me and did not look at the traffic

WEATHER CONDITIONS

1. mountains are absolutely beautiful. Clear as a bell.

2. FREEZING/HARD RAIN

3. hot, hot, hot, hot,

4. sunny, hot, windy

5. clear,beautiful

6. rain rain rain

7. sunny and clear

8. cold, overcast, dark, finger-numbin' fun

9. cold drizzle--and i forgot my damn glove

10. Some sunshine bvut not enuf

APPENDIX D

ACO DATA ANALYSIS

Table D1: Adjustment Factors

Days	Lane	Ramps
Mon.	.000	.000
Tue.	-.001	.004
Wed.	-.001	.002
Thur.	-.002	.009
Fri.	.021	.025
Quarter		
Q3	.000	.000
Q4	-.021	-.044
Q1	-.020	-.046
Q2	-.019	-.021
Lanes		
HOV	0	na
In	-.984	na
Mid	-1.046	na
Out	-.982	na

USING TABLE D1 ADJUSTMENT FACTORS

To use the adjustment factors presented in table D1, merely add (subtract) the appropriate number to the ACO figures presented in Appendix B, based on the aplicable parameters. Continuing the example of the northbound general purpose lanes of I-5 at NE 145th Street during the evening peak in Chapter Three, one would perform the following steps to correct the observed ACO for sample bias.

1. Lookup the ACO value for each quarter of I-5 North, NE 145th Street (Site 14), p.m., northbound general purpose lanes. This yields the following values:
   Q4/92 = 1.12
   Q1/93 = 1.13

2. Adjust the ACO for each quarter according to Table D1 as follows:
   Q4/92 = 1.12 - 0.021 = 1.099
   Q1/93 = 1.13 - 0.020 = 1.110

One can now conclude that ACO slightly increased during Q4/92 through Q1/93.

Note: You have to scramble up the hill on the south side of S. 260th and between the northbound and southbound freeway lanes. Clim over the fence at the top of the hill, and sit behind the jersey barrier at the edge of the freeway (the HOV and fast lanes northbound will be closest to you). Since you are in the freeway right-of-way at this location, you must wear a vest.

APPENDIX H

OBSERVER COMMENTS DURING TRAVEL TIME DATA SESSIONS

Below is a sample of observer comments made during license plate matching travel time data collection. Like vehicle occupancy comments, they fall into three categories of data collection, traffic, and weather conditions. Ellipses represent time gaps between comments made by the observer. Because the length of comments is limited by the program used, words are sometimes cut off.

DATA COLLECTION

1. computer #52 I just found out is 18 minutes faster than #53 which was the other

2. cold, cloudy..... the previous count was lost due to computer malfunction

3. it's not quite daylight yety hard to read plates.....CT COULDNT READ #

4. it's too dark to see anything but busues at this pt.....traffic is very backed up.....the radio said ther is a big wreck up at 405 + 520 - not much traffic here

5. I am too far up and it is too dark to see yet-headlights are impediment also

6. it is very hard to see on this overpass.

7. Hard to see with the big traffic sign in the way...

8. some of thee number keys are wet and not working

9. time to change batteries bacik ijn a moment

10. Head aches too many counts today of TT! Bye!

TRAFFIC CONDITIONS

1. I'm wet ... traffic is slowed slightly ... no real stoppages

2. there is a stsalled car & a stste patrol car off to the right

3. RAINY AND MISERABLE.....TRAFFIC WAS TERRIBLE GETTING HERE SO WE STARTED WAY LATE...IT STAYED PRETTY TER-...RI.....SEE AT ABOUT 6:30 OR SO. ACCIDENTS..

4. cloudy, warm-60 degrees, dry road.....traffic is moving well.....light traffic.....police stopped somebody in the express lane.....traffic is still moving well, below capacity.....another police pulling over somebody in the express lane.....traffic moving well during counting

5. THERE WAS A MAJOR BACKUP ALL DAY AT THIS SITE. IT POURED FOR ABOUT 20 MINUTES.

6. traffic is sluggish. gonna collect some license plates for MH!

7. final tally: two rear-enders, two near misses, 1 frazzled counter

WEATHER CONDITIONS

1. COLD/DARK/RAINY

2. FREEZING COLD/WINDY/GETTING DARK

3. sunny but hell cold!

4. SUNNY AND 80F. MINIMUM WAGE WEATHER.

5. I am late and it is wet. This is a bad day for me.....Traffic is stop and go

6. still dark due to daylight saving time last weekend.....heavy traffic heavy traffic, but it is still moving well.....the rain has stopped for some time

7. cloudy, threatening; summer is grand

8. sunny, tantalizing, frenetic, abusive, c.....no problem : YOW! sunshine ... on my shoulder ... makes me happy

APPENDIX I

SAMPLE SURVEY

Washington State Department of Transportation

University of Washington

Washington State Transportation Center

HIGH OCCUPANCY VEHICLE LANE ANALYSIS
PUBLIC OPINION SURVEY

The Washington State Department of Transportation and the Washington State Transportation Center at the University of Washington are working together to study the high occupancy vehicle (HOV) lanes, also known as carpool lanes. We would like to understand your driving preferences and your perception of HOV lane use and effectiveness.

Please give this survey to the person in your household who most often uses freeways between the hours of 6:00-9:00 AM and 3:00-6:00 PM in the Puget Sound area. Ask him or her to fill out the survey and return it by mail within one week. We would appreciate your response. No postage is necessary.

Your answers will not be associated with your name. Please feel free to contact either Eldon L. Jacobson at (206) 685-3187 or William Brown at (206) 616-9183 between 8:00 AM and 4:00 PM if you wish to discuss the survey.

Section A: Your Commute Trip

1. Indicate your ***usual*** mode of driving when using area highways between 6:00-9:00 AM and 3:00-6:00 PM.

___ Drive alone
___ Carpool - you and 1 other person
___ Carpool - you and 2 or more other people
___ Vanpool
___ Bus
___ Bicycle, Walk
___ Motorcycle
___ Other

2. Have you ever used HOV lanes while traveling in the Puget Sound area between 6:00-9:00 AM and 3:00-6:00 PM?

YES___ No___ (*If NO, please proceed to Question 3*)

How do you use HOV Lanes? Please indicate all that apply.

___ on a bus
___ in a 2-person carpool
___ in a 3-person carpool
___ in a vanpool
___ alone in a car
___ on a motorcycle

On which freeway do you usually use HOV lanes?

___ I-5 north of Seattle
___ I-5 south of Seattle
___ I-90
___ SR 520
___ I-405 north of I-90
___ I-405 south of I-90
___ SR 16
___ SR 167

3. Do you ever ***not*** use the HOV lanes even though you have enough people in your vehicle to qualify for them between 6:00- 9:00 AM and 3:00-6:00 PM?

Yes___ No___ If yes, why? (check all applicable)

___ the HOV lanes are slower than regular lanes
___ too much trouble to change lanes
___ the HOV lanes are not safe
___ all traffic moves fast enough
___ forget to use the HOV lanes
___ other _____

Section B: Your Opinions

4. Place an "X" by the ***three options*** that you think would most likely make HOV lanes more attractive for carpooling, vanpooling, or bus riding.

___ Wider and safer HOV lanes.

___ Construct direct entrance and exit ramps that connect with inside HOV lanes.

___ HOV lanes on the outside (right side) of the freeway.

___ HOV lanes on the inside (left side) of the freeway.

___ Park & ride lots near freeway entrances/exits.

___ Better police enforcement of violations.

___ Employers' help with paying for part or all of bus passes, vanpooling fares, or parking for carpoolers.

___ Increased frequency of bus service.

5. Please indicate the extent to which you agree or disagree with the following statements.

	Agree Strongly	Agree	Neutral	Disagree	Disagree Strongly
a. HOV lanes are a good idea.	___	___	___	___	___
b. Vehicles dart in and out of HOV lanes too often for the lanes to be safe.	___	___	___	___	___
c. HOV lanes help save all commuters a lot of time.	___	___	___	___	___
d. Constructing HOV lanes is unfair to taxpayers who choose to drive alone.	___	___	___	___	___
e. Existing HOV lanes are being adequately used.	___	___	___	___	___
f. HOV lane violators commit a serious traffic violation.	___	___	___	___	___
g. HOV lane violators are common during the commute hours.	___	___	___	___	___
h. Many more people would carpool if the HOV lanes were more widespread.	___	___	___	___	___
i. HOV lanes should be opened to all traffic.	___	___	___	___	___
j. HOV lanes are convenient to use.	___	___	___	___	___
k. HOV lane construction should continue, in general.	___	___	___	___	___
l. HOV lanes should be opened to all traffic during non-commute hours.	___	___	___	___	___
m. The HERO program helps reduce HOV lane violations. [by encouraging commuters to report HOV violators at (206) 764-HERO]	___	___	___	___	___

Section C: About Yourself (Optional)

6. Are you ___ Male ___ Female

7. What is your age? ___ under 31 ___ 31-40 ___ 41-50 ___ 51-64 ___ 65+

8. What is your highest level of education?

___ did not finish high school
___ high school
___ community college or trade school
___ college/university
___ post graduate

9. Including yourself, how many people live in your household? ____

10. How many people living in your household are over age 15? ____

11. How many people living in your household work outside the home? ____

12. How many vehicles (in working order) do you have? ____

13. What is the Zip Code of your work place? _____ your home? _____

14. Which freeways do you frequently use while traveling in the Seattle area between the hours of 6:00-9:00 AM and 3:00-6:00 PM? Please indicate whether you use each freeway for commute trips and/or for other trips.

Commute	Other		Commute	Other	
___	___	I-5 north of Seattle	___	___	SR 520
___	___	I-5 south of Seattle	___	___	SR 16
___	___	I-405 north of I-90	___	___	SR 167
___	___	1-405 south of I-90	___	___	SR 410
___	___	I-90	___	___	SR 512

15. Are some sections of the HOV system too congested? If so, where?

_____
_____
_____
_____

16. Comments:

_____
_____
_____
_____
_____

Thank you for taking the time to complete this survey. When you are finished, please refold the survey form so that the 'University of Washington' address is displayed, secure with tape, and drop it in a mailbox at your convenience. No postage is neccessary.

APPENDIX J

COMMENTS OF SURVEY RESPONDENTS

The following are examples of respondent's written comments. The comments generally fall into four categories; support for HOV lanes, opposition to HOV lanes, solutions to traffic problems, and miscellaneous. Respondents' comments are overwhelmingly in opposition to HOV lane restrictions and further HOV lane construction. Ten representative comments illustrate respondents' input.

1. Keep SOVs out of bus lane, If buses are more frequent, ridership might increase. I favor congestion pricing to discourage SOVs.

2. I think HOV lanes are great and should be added on all major highways. It may take higher gas prices to entice more people to carpool.

3. When I am stuck in traffic and am in a hurry and cars with one person whiz past in the HOV lane it is VERY frustrating. The HOV lanes should be enforced strictly or eliminated. The way it is now scoff-laws use HOV lanes and get places quickly.

4. HOV lanes should be open to all traffic during non-commute hours. (all hours except 6 am to 9 am and 3 pm to 6 pm)

5. All HOV lanes should be the same - 2 or more people. It's confusing when some lanes are signed for 3+ carpools and other are for 2+ carpools.

6. Traffic problems will not be solved until we have some other mass transit besides buses. Having sat on buses stuck in traffic, I know that buses are not the answer.

7. I believe that HOV lanes help relieve congestion, but they should not be the focus of decreasing congestion. A wide variety of approaches are needed: improved bus lines, short run trolleys, expansion of existing rail transport, increasing safety of bicycle routes, and encouraging carpools and vanpools.

8. I think a lot of commuters think the HOV lanes are for speeding. I like the lanes for convenience but it really scares me with the traffic darting back and forth.

9. I often use the HOV lane when I have my small son in the car with me. I am sure to some driving by that it looks like I'm alone. That is why I don't think observation and mailing a ticket is not [sic] a good idea.

10. I am a real estate appraiser and use these freeways to travel to and from appointments. Due to my profession I am not able to use the HOV lanes on a regular basis. It amazes me the number of multiple occupant vehicles that do not use HOV lanes. I would be interested in knowing why they don't.

11. Too many single drivers abuse the carpool lanes in traffic back-ups. There seems to be no penalty for drivers that do this. I think it would be best to either enforce stiff penalties or get rid of the HOV lanes altogather.

12. HOV lanes need to be on the inside of highways. With current configuration, HOV lanes bunch up at all on/off ramps making the normal lanes quicker.

13. Road construction on expansion of HOV lanes is proceeding at an unacceptably slow pace. This is causing unnecessary delays in commutes.

14. Switching carpool lanes from left to right side of freeway at Renton S-curves is a real challenge. I don't feel that this area moves efficiently.

15. The second person of a carpool should be at least old enough to drive a car. Otherwise HOV lanes are not effective in reducing the number of cars on the freeway.

16. Make 2 or more lanes of the freeway system HOV lanes, therefore creating a cause to use the transit system or carpooling. The only way your going to get SOVs off the road is to mandate legislation against them. The sooner the better.

17. State needs to make the violation fine higher - in California it's like $250 or higher - they don't have people violating like they do here.

18. The reporting procedure for 764-HERO is far too complicated. The license plate should be sufficient. Vehicle location and description of car is not easily to ascertain nor relevant.

19. I would like to see consideration in this survey for those people who do not commute directly to and from work every day, simply to factor in this section of the population, instead of assuming that all people commute directly to and from work.

20. Need to install glare barriers on jersey barrier between adjecent HOV lanes. It's dangerous driving in dark wet conditions looking into the headlights of oncoming cars. Also, drainage is a problem with the HOV lanes between Northgate and Lynnwood. I don't use the carpool lane in such conditions.
